## 1. Implementation Details

Here we describe more details of the model implementation. As introduced in Section 3, the 3D proxy provides depth, texture, and also light/viewpoint predicted from  $\Phi^l, \Phi^\omega$ , respectively. During the learning procedure of ARN and GRN, we directly use the  $l_o, \omega_o$  from pre-trained  $\Phi^l, \Phi^\omega$  proxy for rendering. Then, we jointly train  $\Phi^l, \Phi^\omega$  with ARN and GRN in the final mutual learning process.

For the lighting  $\Lambda$  and rasterization  $\Pi$  operation used in Eqns. (1) and (2), we follow a same setting as Unsup3D [6]. Here we provide more details. The lighting  $\Lambda$  is conducted at the canonical view, where we shade the canonical albedo  $a$  with the predicted light  $l$  by the Lambertian function  $f_{lam}$ . Concretely, we first transform the predicted canonical depth  $d$  to the normal  $n$ , then perform  $\mathbf{S} = f_{lam}(n, l)$  to get a shading map  $\mathbf{S}$ . Finally, the canonical texture  $t$  is obtained by  $t = \mathbf{S} \odot a$ . For the rasterization  $\Pi$  function, we set the Field of View (FOV) of the camera as  $10^\circ$  to calculate the camera matrix. The corresponding projection and warping operations is implemented by neural mesh renderer [4].

## 2. Details of the Experiment on MICC

In Fig. 1 of the main paper, we perform a cross-view geometry analysis on MICC [1] dataset. MICC is a 3D face dataset containing 53 subjects with its ground truth 3D mesh acquired from a structured light scanning system. Similar to [3], we render a provided face to  $-45^\circ, 0^\circ$ , and  $+45^\circ$  respectively, each of which contains 3 rendered faces. To evaluate the performance of cross-view geometry modelling, we use the image of one pose for reconstruction and measure the modelled geometry on the other two poses. For instance, we first use the image of  $0^\circ$  as input to recover the geometry, and then calculate the errors with ground truth geometry of  $-45^\circ$  and  $+45^\circ$ , respectively. The errors are then averaged as the final result. In the experiment, we evaluate our method, Unsup3D [6] and LAP [7], each of which is directly tested on MICC using the pre-trained weights without fine-tuning.

We further show examples in Fig. 1. As illustrated, our method models better facial geometry and organ shapes,

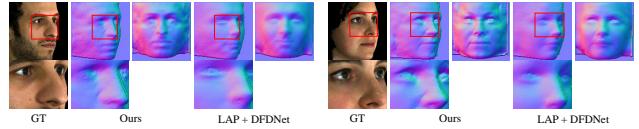

Figure 1. Visual comparison on MICC dataset.

while LAP [7] cannot precisely recover the corresponding face structure.

## 3. More Results

In Fig. 2, we show more results and comparisons with the state-of-the-art methods. Our method predicts finer details and more precise facial shapes against the degraded images.
