1. Introduction

In this supplementary material, we provide the detailed description of the network structure of our late fusion CNN and additional image matting results on the human matting testing dataset, the composition-1k testing dataset and Internet images.

2. Network Structure Details

The structures of the segmentation network and the fusion network are shown in Tab. 1 and Tab. 2, respectively. In the segmentation network, we use DenseNet-201 [2] as our encoder, and the growth rate of the dense block is set to 32. We also adapt the technique from feature pyramid network [3], adding side losses on different output scales. Since the network structures of two decoder branches in the segmentation network are same, we only describe the details of one decoder branch in Tab.1. The fusion network is a fully convolutional network without downsampling to avoid the loss of details.

Note that we take the input image of the resolution 512×512 as an example in Tab. 1 and Tab. 2. The resolutions of output feature maps in the network are therefore computed accordingly. Since our network is fully convolutional, the RGB images whose longer side is less than or equal to 800 pixels can be input to the network.

3. Additional Testing Datasets Matting Results

From Fig. 1 to Fig. 3, we show more results of our method on the human matting testing dataset. In Fig. 4 and Fig. 5, we show more results of our method on the composition-1k testing dataset [5]. We also compare our method with two other approaches, DCNN [1] and DIM [5]. All trimaps are generated by dilating 25 pixels from the ground-truth matte.

4. Additional Internet Images Matting Results

In Fig. 6 and Fig. 7, we show the results of our method on images collected from the Internet. Our collection contains different types of foreground objects including human portraits, human full-body images, plants, nets, plush toys, animals and glasses. Human portraits and full-body images are inferred with the model that is trained on our human image matting dataset. Other images are inferred with the model that is trained on the DIM dataset.

Table 1. Architecture of the segmentation network. Note that we only show the foreground decoder branch in this table, the background decoder branch has the similar structure which is not shown here. The input of the network is set to be a $512 \times 512 \times 3$ RGB image as an example. The resolution can be changed since our network is fully convolutional. The *dense block* and *growth rate* in this table are the same as in the DenseNet architecture [2]. All convolutional layers except those in the *Side Loss* are followed by the batch-normalization layers and ReLU activation layers. All Side Loss blocks are followed by a sigmoid activation function for calculating the segmentation loss. Since the network structures of two decoder branches in the segmentation network are same, we only describe the details of one decoder branch. The output of the *side0* block is the foreground/background probability map.

Block name	Output size	Filter size
rgb_conv+BN+ReLU	$512 \times 512 \times 128$	$3 \times 3, 128$
		$3 \times 3,256$
fusion_conv1+BN+ReLU	$512 \times 512 \times 256$	input: concatenate
		FG_deconv0, BG_deconv0, rgb_conv
fusion_conv2+BN+ReLU	$512 \times 512 \times 128$	$3 \times 3, 128$

fusion_conv4+BN+ReLU	$512 \times 512 \times 64$	$3 \times 3,64$
fusion_conv5+BN+ReLU	$512 \times 512 \times 256$	$3 \times 3,256$
fusion output	$512 \times 512 \times 1$	$3 \times 3, 1$
lusion_output	012 × 012 × 1	output: sigmoid

Table 2. Architecture of the fusion network. The inputs of the network are set to be a $512 \times 512 \times 3$ RGB image and two $512 \times 512 \times 128$ decoded features, *FG_deconv0* and *BG_deconv0*, from the foreground and background decoder branches (see *deconv0+BN+ReLU* block in one decoder branch described in Tab. 1). All convolutional layers except the last one are followed by the batch-normalization layers and ReLU activation functions. The last convolutional layer in the *fusion_output* block is followed by a sigmoid activation function for calculating the fusion loss. The output of the *fusion_output* block is the fusion weight map.
