

## **Motivation**

Typical sequence classification models are designed for well-segmented sequences, which often need manual and time-consuming pre-processing.

Goal: We propose Temporal Attention-Gated Model (TAGM) to better deal with **noisy** or **unsegmented** sequences by automatically locating the salient segments.

Our model can automatically extract the salient frames from the noisy raw input sequences and learns an effective hidden representation for the top classifier. The wider the arrow is, the more salient the frame is and the more the information is taken into account for prediction.

# Contributions

- Automatically capture salient parts of the input noisy sequence to achieve better performance.
- Inferred meaningful attention scores provide interpretation for the informativeness of each time step.
- Less parameters leading to faster training and better generalizability with less training data.
- Generalization across different tasks and modalities.
- Code available<sup>1</sup>.

## Model

# **Recurrent Attention-Gated Units**

To learn an effective hidden representation.

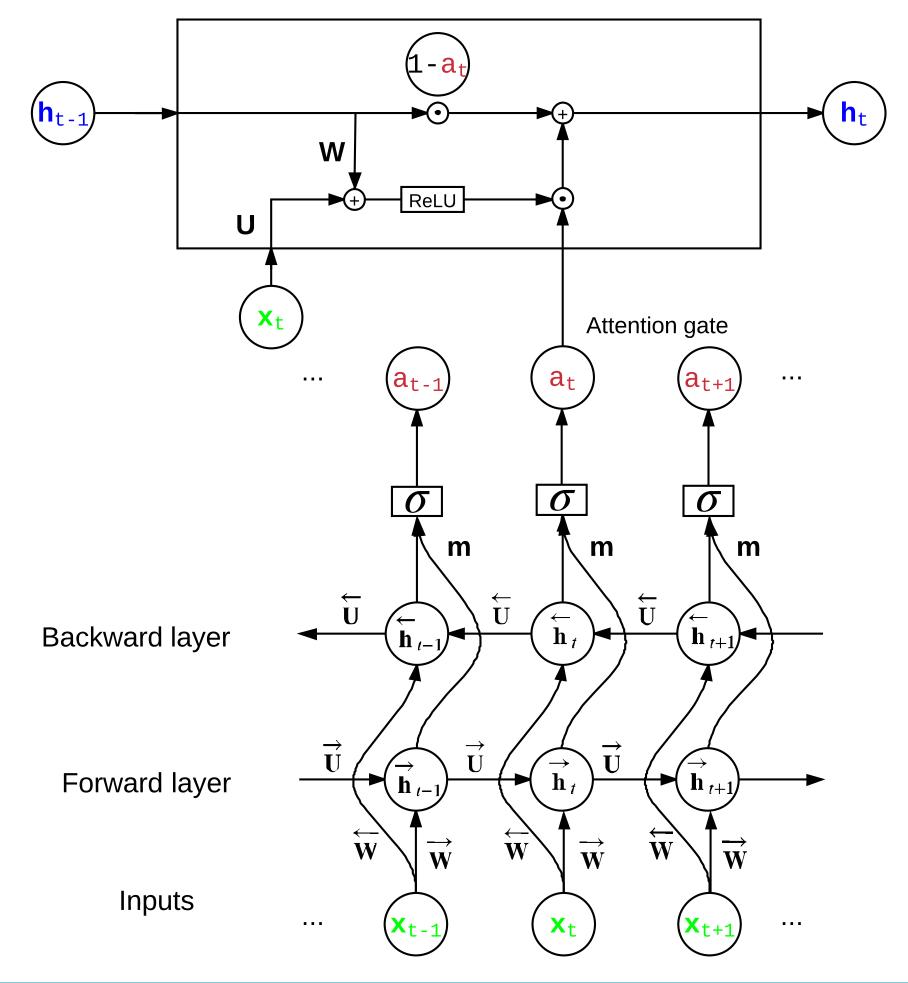

$$\mathbf{h}_t = (1 - a_t) \cdot \mathbf{h}_{t-1} + a_t \cdot \mathbf{h'}_t$$

$$\mathbf{h'}_t = g(\mathbf{W} \cdot \mathbf{h}_{t-1} + \mathbf{U} \cdot \mathbf{x}_t + \mathbf{b})$$

# **Temporal Attention Module**

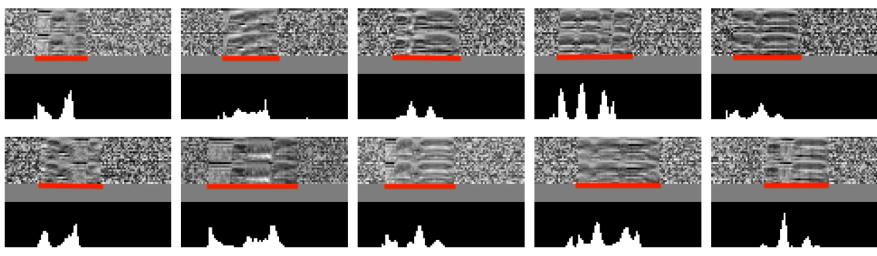

To extract salient frames.

$$a_{t} = \sigma(\mathbf{m}^{\top}(\vec{h}_{t}; \vec{h}_{t}) + b)$$
  
$$\overrightarrow{h}_{t} = g(\overrightarrow{\mathbf{W}}\mathbf{x}_{t} + \overrightarrow{\mathbf{U}}\overrightarrow{h}_{t-1} + \overrightarrow{\mathbf{b}})$$
  
$$\overleftarrow{h}_{t} = g(\overleftarrow{\mathbf{W}}\mathbf{x}_{t} + \overleftarrow{\mathbf{U}}\overrightarrow{h}_{t+1} + \overrightarrow{\mathbf{b}})$$

# **Experiments**

We perform experiments with TAGM on three datasets to show generalization across different tasks and modalities.

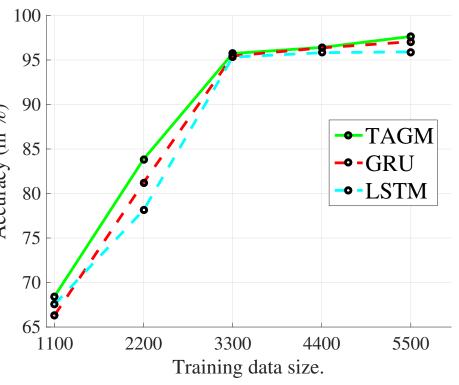

## Sentiment Analysis

## Speech Recognition

Dataset: Noisy Arabic spoken digit dataset (8800 utterances, 10 digits) Feature: MFCCs

The visualization of attention weights of TAGM on 10 samples (one sample for each digit). For each subfigure, the top subplot shows the spectrogram of the original sequence data while the bottom subplot shows the attention values over time. The red lines indicate the groundtruth of salient segments.

The classification accuracy on the noisy Arabic spoken digit dataset as a function of the size of training data.

Dataset: Stanford Sentiment Treebank (11,855 review sentences, binary-classification or fine-grain Feature: 300-d glove word vectors

The visualization of attention weights of TAGM. The scores displayed are the groundtruth label indicating the sentiment for this review. Darker color indicates smaller scores.

## **Event Recognition**

Dataset: Columbia Consumer Video Database (9317 videos, 20 events)

Feature: CNN features from pre-trained AlexNet model

The attention weight is indicated representative frames. Our TAGM is able to capture the action of '**riding bike**' for the event 'biking', 'cake' for the event 'birthday' and 'infield zone' for baseball
