1. Proof of Lemma 1

**Lemma 1.** Assume that the loss \( L(\theta(x), y) \) is convex in its first argument and that there exists a \( \lambda \in \mathbb{R}^n \) where \( \lambda \geq 0 \) and \( \lambda^T 1 = 1 \), such that the target distribution is exactly equal to the mixture of source distributions, i.e \( Q_T = \sum_{i=1}^n \lambda_i Q_S^i \). Set the target predictor as the following convex combination of the optimal source predictors

\[
\theta_T(x) = \sum_{k=1}^n \frac{\lambda_k Q_S^k(x)}{\sum_{j=1}^n \lambda_j Q_S^j(x)} \theta_S^k(x).
\]

Recall the pseudo-labeling loss (10). Then, for this target predictor, over the target distribution, the unsupervised loss induced by the pseudo-labels and the supervised loss are both less than or equal to the loss induced by the best source predictor. In particular,

\[
\mathcal{L}(Q_T, \theta_T) \leq \min_{1\leq j \leq n} \mathcal{L}(Q_T, \theta_S^j).
\]

**Proof.** We can see that the left-hand-side of the inequality can be upper-bounded by some loss as follows,

\[
\begin{align*}
\mathcal{L}(Q_T, \theta_T) &= \int_x Q_T(x) L(\theta_T(x), y) \, dx \\
\leq& \int_x Q_T(x) L\left( \sum_{i=1}^n \frac{\lambda_i Q_S^i(x)}{\sum_{j=1}^n \lambda_j Q_S^j(x)} \theta_S^i(x), y \right) \, dx \\
=& \int_x Q_T(x) \sum_{i=1}^n \frac{\lambda_i Q_S^i(x)}{\sum_{j=1}^n \lambda_j Q_S^j(x)} L(\theta_S^i(x), y) \, dx \quad \text{(from Jensen’s inequality)} \\
=& \sum_{i=1}^n \lambda_i \int_x Q_S^i(x) L(\theta_S^i(x), y) \, dx \quad \text{(from distribution assumption)} \\
=& \sum_{i=1}^n \lambda_i \mathcal{L}(Q_S^i(x), \theta_S^i).
\end{align*}
\]

Now for the R.H.S. we can write this loss as follows,

\[
\begin{align*}
\mathcal{L}(Q_T, \theta_S^i) &= \int_x Q_T(x) L(\theta_S^i(x), y) \, dx \\
=& \int_x \sum_{i=1}^n \lambda_i Q_S^i(x) L(\theta_S^i(x), y) \, dx \\
=& \sum_{i=1}^n \lambda_i \int_x Q_S^i L(\theta_S^i(x), y) \, dx \\
=& \sum_{i=1}^n \lambda_i \mathcal{L}(Q_S^i(x), \theta_S^i).
\end{align*}
\]

Now recall from main paper that,

\[
\theta_S^k = \arg\min_{\theta} \mathcal{L}(Q_S^k, \theta) \quad \text{for} \quad 1 \leq k \leq n.
\]

This means \( \theta_S^k \) is the best predictor for the source \( i \), which has distribution \( Q_S^i \). Thus we find that \( \mathcal{L}(Q_S^k, \theta_S^k) \leq \mathcal{L}(Q_S^i, \theta_S^i) \forall j \), which implies \( \sum_i \lambda_i \mathcal{L}(Q_S^i, \theta_S^i) \leq \sum_i \lambda_i \mathcal{L}(Q_S^k, \theta_S^k) \). This further implies that \( \mathcal{L}(Q_T, \theta_T) \leq \min_{1 \leq j \leq n} \mathcal{L}(Q_T, \theta_S^j) \), which in turn concludes the proof \( \mathcal{L}(Q_T, \theta_T) \leq \min_{1 \leq j \leq n} \mathcal{L}(Q_T, \theta_S^j) \). Finally, suppose the entries of \( \lambda \) are strictly positive and let \( \beta = \arg\min \mathcal{L}(Q_T, \theta_S^j) \). Observe that, if there is a source \( i \) such that the strict inequality \( \mathcal{L}(Q_S^i, \theta_S^i) < \mathcal{L}(Q_S^k, \theta_S^k) \) holds, then the main claim of the lemma also becomes strict as we find

\[
\mathcal{L}(Q_T, \theta_T) \leq \sum_i \lambda_i \mathcal{L}(Q_S^i, \theta_S^i) < \sum_i \lambda_i \mathcal{L}(Q_S^k, \theta_S^k) \leq \min \mathcal{L}(Q_T, \theta_S^k).
\]

Verbally, this strict inequality has a natural meaning that the model \( j \) is strictly worse than model \( i \) for the source data \( i \). 

2. Detailed steps of combination rule under source distribution uniformity assumption

See the discussion after Lemma 1 in the main paper for reference.

\[
\theta_T(x) = \sum_{k=1}^{n} \frac{\lambda_k Q_k^S(x)}{\sum_{j=1}^{n} \lambda_j Q_j^S(x)} \theta_k^S(x)
\]

\[
= \sum_{k=1}^{n} \frac{\lambda_k c_k U_k(x)}{\sum_{j=1}^{n} \lambda_j c_j U_j(x)} \theta_k^S(x)
\]

\[
= \sum_{k=1}^{n} \frac{\lambda_k c_k}{\sum_{j=1}^{n} \lambda_j c_j} \theta_k^S(x)
\]

(3)

3. Additional Experiments

Figure 1: **Weights as model selection proxy.** The weights learnt by our framework on Office-31 correlates positively with the unadapted source model performance. (Left axis corresponds to the red plot and right to the blue plot, best viewed in color.)

From Figure 1, we can clearly see that for the model which gives higher accuracy for the unadapted scenario, it is automatically given higher weightage by our algorithm. As a result, we can easily infer about the quality of the source domain, in relation to the target, from the weights learnt by our framework.

**Effect of weight on pseudo-labeling.** We investigate the effect of the weight \( \lambda \) on \( L_{pl} \). We perform experiments on the Office dataset by varying the value of \( \lambda \) and plot the results in Figure 2. As shown in the plot, the proposed method performs best at \( \lambda = 0.3 \)

Figure 2: **Effect of \( \lambda \).** The variations in classification as the weight on \( L_{pl} \) is varied. (Best viewed in color)

**Effect of outlier source models.** Our method is clearly robust to outlier source models. In Table 2 of the main paper, when **MNIST-M** is the target, transferring from only **USPS**, leads to an extremely poor performance of 21.3% - here, USPS is a strong outlier. Despite the presence of such a poor source, our framework is mostly able to correctly negate the transfer from USPS, achieving a performance of 93%, close to the best source performance of 94%. On removing **USPS** as a source, **DECISION** outperforms the best source by achieving an accuracy of 94.5%. In the future, we plan to actively use the weights to simultaneously remove poor sources while adaptation in order to boost the performance.

DomainNet [32]: This is a relatively new and large dataset where there are six domains under the common object categories, namely quickdraw (Q), clipart (C), painting (P), infograph (I), sketch (S) and real (R) with a total of 345 object classes in each domain. Experimental results on this dataset are shown in Table 1. Our method consistently outperforms the best adapted source baselines (SHOT-best) except for infograph as a target. However the average performance over all the domains as target is slightly less than the SHOT-Ens. Note that for quickdraw and clipart as target, our method outperforms all the state of the art methods including source free and with source data single and multi source state-of-the-art DA methods.

Distillation. Our results on using the distillation strategy outlined in Section 5.4 of the main paper are shown in Table 2. Despite the model compression, the performance remains consistent.
