This supplemental document provides an ablation study (Appendix A), extensive results (Appendices B and C), and further implementation details (Appendix D). Please also refer to our video on our project page¹ that demonstrates our method in action.

A. Ablations

Figure 1: **Farthest Point Keypoint regularizer ablation.** We investigate the influence of the number J of sampled farthest points q used for the keypoint regularizer (Section 3.2 of the main paper) on the quality of discovered unsupervised keypoints. We show unsupervised 3D keypoints trained using two versions of regularization. First, we set the number of sampled farthest points to double of the number of keypoints (a, c). This is the setup that we use throughout the paper. Second, we set the number of sampled farthest points to the number of points in the point cloud representing the shape. This essentially results in a regularizer that is minimizing the Chamfer distance between the unsupervised keypoints and the object point cloud. Although the learned unsupervised keypoints have a good coverage (b, d) they are not as equally spaced and characteristic of the shape as (a, c).

Varying number of regularizing points. We examine the importance of the number of sampled farthest points q on the quality of keypoint regularization (Section 3.2 of the main paper). Figure 1 shows the effect of different numbers of sampled farthest points on the discovered keypoints. Using a high number of sampled farthest points in the regularization fails to learn keypoints that are equally spaced and characteristic of the underlying shape.

Varying number of keypoints. We vary the number of unsupervised keypoints discovered by our method. Figure 2 shows that our keypoints remain semantically consistent for different numbers of discovered keypoints.

* Work done while interning at Google Research.

B. Shape Control via Unsupervised 3D Keypoints

We show user guided interactive shape control in our supplementary video on our project page. Figure 5 shows frames captured from user-guided interactive shape editing. Editing using our keypoints is fast and intuitive while preserving the character and details of the original shape.

C. Unsupervised 3D Keypoints

We show extended quantitative results for semantic part correspondence experiment and detailed correlation tables in Figure 3 for the ShapeNet Car category. Figures 6 to 10 show extensive *randomly* sampled qualitative test results for our unsupervised 3D keypoints.

D. Implementation Details

Our model assumes that the shapes are aligned (in the same orientation). The initial cage is a 42-vertex icosphere. We limit the influence matrix W to influence at most M nearest cages vertices (Section 3.1) per each keypoint, with $M = \lfloor C/K \rfloor$, where C is the number of cage vertices and K is the number of discovered keypoints. We use a learning rate of 0.001. The scalar loss coefficients (Section 3.2) α_{kpt} and α_{inf} are set to 1.0 and 10^{-6} respectively. Figure 4 shows detailed description of network architectures used for the keypoint predictor Φ and the influence predictor Γ .

Datasets. KeypointNet [7] dataset contains semantic 3D keypoint annotations for ShapeNet dataset [1]. Some models in KeypointNet are missing full keypoint annotations, therefore we use a subset of annotated keypoints that are contained in at least 80% of the models. KeypointNet also does not follow the standard training and testing splits from ShapeNet. We resample the KeypointNet dataset splits to make it compatible with the original ShapeNet splits.

(a) predicted unsupervised keypoints

# of unsupervised keypoints	4	8	12	16
PCK@0.05	0.56	0.61	0.71	0.71

(b) quantitative evaluation

Figure 2: **Varying number of keypoints.** The figure (a) shows the effect of different number of discovered keypoints (4, 8, 12, 16 from the top). The results are shown on randomly sampled results for ShapeNet Airplane category. Results in the table (b) are in terms of PCK@0.05 on airplanes from the KeypointNet dataset.

(b) average unsupervised keypoints correlation

Figure 3: **Semantic part correspondence.** We evaluate semantic part correspondence for the ShapeNet Car category. The tables (a) shows the frequency of each unsupervised keypoint [kp*] being associated with a given object part. Chen et al. [2] show worse performance in this task because that methods tends to predict keypoints inside the object far from the annotated object surface. We also report the average unsupervised keypoints correlation for each category (b). ↑ is better.

Operation	Kernel	Output channels	Output size	Activation
