Example of FEC dataset

We demonstrate a triplet example from the FEC \cite{4} dataset to illustrate the similarity between Anchor, Positive, and Negative images. As observed, Anchor is more similar to Positive and more different from Negative.

\includegraphics[width=\textwidth]{example.png}
\caption{An example of FEC dataset. Anchor and Positive are the more similar images compared with Negative.}
\end{figure}

Implementation Details

We have described the implementation details for FEC \cite{4} triplet prediction in the main text. Network parameters of our model are 55.93M, compared to FECNet with 223.48M. Our flop is 6.32GMac and FECNet is 8.18GMac. Here, we will supplementally describe the implementation details for applications of emotion recognition and face manipulation.

For emotion recognition, we use the Deviation Learning Network (DLN) without the crowd layer as backbone, and a Softmax layer, in replacing of the layer that produces the expression embedding, to calculate the occurrence probabilities of 7 emotions. The DLN is trained on the AffectNet \cite{3} training set and RAF-DB \cite{2} training set for 10 epochs with a learning rate of 0.001 using SGD optimizer with a momentum of 0.9. The batch size is set to 30. The DLN is supervised by the weighted cross-entropy loss.

For face manipulation, we make use of the pix2pixHD Network \cite{5} and train it by Adam with a learning rate of $2 \times 10^{-4}$ for Generator and Discriminator. The pipeline can be seen in Fig. 2. We use the supervised data of RaFD \cite{1} for generating manipulated faces during training while we generate faces manipulated by different identities’ expression when testing.
