1. Additional Ablation study

The Number of Information Content Sets in Eq.2 is studied in Table 1, which shows the model training performance (in terms of mean AUC testing set results) and number of training stages using 2% and 20% labelled set on Chest X-ray14 [2]. The default setting used in the paper is to have three information content sets, namely low, medium, high. As shown in Table 1, the selection of only two sets produces the worst results because the pseudo-labelled set becomes less informative and imbalanced. The selection of four sets produces similar results as with three sets. However, with this additional set, the number of new pseudo labelled samples are greatly reduced for every training stage, forcing the number of training stages to grow. Hence, by selecting three sets we reach a good balance between training time and accuracy.

2. Data Distribution

In Figure 1, we show the data distribution of all classes of Chest X-ray14 (plus the class ‘No Findings’) [2]. Notice that the selection of high information content samples (blue) creates a more balanced distribution compared with the selection of low information content (yellow) or the original data distribution (green).

3. Visualization of Classification Results

Figure 2 shows examples of pseudo-labels produced by our density mixup for both Chest Xray-14 [2] (top) and ISIC2018 [1] (bottom) datasets.
