A. Experimental Details

We follow the implementation details of the official MAE [28] for all pre-training and fine-tuning. Meantime, we follow the implementation of bootMAE [20] for settings of segmentation tasks. While MAE uses only ViT-B and ViT-L, we also use ViT-S [60].

For pre-training, we use the same effective batch size of 4096 as MAE with accum_iter, *e.g.*, 256 (batch_size_per_gpu) \times 8 (GPUS) \times 2 (accum_iter). The detail configurations is listed in Table 9. For end-to-end fine-tuning, we provide the configures in Table 10 for different backbones.

| m 1 1 | 0 | D | | • |
|--------------|----|-------|----------|-----------|
| Table | 0 | Dro | training | cottinge |
| Table | 7. | L 1C- | uannng | SELUII25. |

| training epochs | 300(S), 100 (B,L) |
| label smoothing | 0.1 |

B. Pytorch Code for Adversarial Training

We also provide the simplified pytorch implementation for adversarial training in GAN-MAE model, to illustrate the optimization process more expressly.

Figure 4. **Performance comparison given the same compute budget with ViT-B structure**. With the advancing of discriminator capacity, the performance gains consistently increase.

| Lis | Listing 1: Example Pytorch Code | | | | |
|-----|---------------------------------|--|--|--|--|
| 1 | mode | el = mae_gan_vit_base_patch16() | | | |
| 2 | | | | | |
| 3 | opti | <pre>imizer_gen = AdamW(generator_module.</pre> | | | |
| | | parameters(), lr=lr) | | | |
| 4 | opti | imizer_disc = AdamW(discriminator_module. | | | |
| | | parameters(), lr=lr) | | | |
| 5 | | | | | |
| 6 | for | raw_img in dataloader_pretrain: | | | |
| 7 | | # generator training | | | |
| 8 | | optimizer_gen.zero_grad() | | | |
| 9 | | <pre>gen_loss, corrupt_img, mask = model.</pre> | | | |
| | | forward_with_generator(raw_img) | | | |
| 10 | | gen_loss.backward() | | | |
| 11 | | optimizer_gen.step() | | | |
| 12 | | | | | |

| | | <pre>mask.detach()</pre> | | | |
| 15 | | <pre>optimizer_disc.zero_grad()</pre> | | | |
| 16 | | disc_loss = model. | | | |
| | | forward_with_discriminator(| | | |
| | | corrupt_img, mask) | | | |
| 17 | | disc_loss.backward() | | | |
| 18 | | optimizer_disc.step() | | | |

C. Extra Experimental Results

Compute-matched Comparison. We also chose to measure compute usage in terms of floating point operations (FLOPs) because it is a measure agnostic to the particular hardware, low-level optimizations, etc. We plot the computation-performance curve in Figure 4, and we can observe that GAN-MAE outperforms the MAE persistently under the same computation budget in the downstream classification task.

Linear Probing Evaluation. We conduct the linear probing experiment to evaluate the semantic level of a representation, and the results are listed in Table 11. As can be seen, our method pre-trained on 800 epochs achieves a considerable gain (+4.0%) compared with MAE baselines, even on 1600 epochs.

Table 11. Linear probing evaluation on ImageNet-1K. We report the top-1 accuracy for classification with different ViT structures.

| Method | Pre-train epochs | ViT-B | ViT-L |
|---------|------------------|-------|-------|
| MAE | 800 | 64.4 | 73.5 |
| MAE | 1600 | 67.8 | 75.1 |
| GAN-MAE | 800 | 69.3 | 77.5 |
