

STEPS: Sequential Probability Tensor Estimation for Text-to-Image Hard Prompt Search

Supplementary Material

6. Conditional Sampling with Tensor Train Structure

In this section, we present more details on how to efficiently sample the indices using the discrete distribution with TT structure. The sampling process primarily follows the approach outlined in [9]. Given a discrete multivariate probability distribution $p(x_1, x_2, \dots, x_d)$, we sample from it using conditional distribution:

$$p(x_1, x_2, \dots, x_d) = p(x_1)p(x_2|x_1) \cdots p(x_d|x_1, \dots, x_{d-1}), \quad (13)$$

where $p(x_k|x_1, x_2, \dots, x_{k-1})$ is given by

$$p(x_k|x_1, x_2, \dots, x_{k-1}) = \frac{p(x_1, x_2, \dots, x_k)}{p(x_1, x_2, \dots, x_{k-1})}. \quad (14)$$

Before sampling process, we first calculate $(d-1)$ matrices $\mathbf{Q}_k \in \mathbb{R}^{r_{k-1} \times 1}$:

$$\mathbf{Q}_k = \sum_{i_k} \mathcal{G}(:, i_k, :) \mathbf{Q}_{k+1}, k \in 2, 3, \dots, d. \quad (15)$$

In addition, given the sampled indices (x_1, x_2, \dots, x_k) , we compute the $\mathbf{P}_k \in \mathbb{R}^{1 \times r_k}$ as

$$\mathbf{P}_k = \mathcal{G}(1, x_1, :) \mathcal{G}(:, x_2, :) \cdots \mathcal{G}(:, x_k, :). \quad (16)$$

The sampling procedure is computed using Eq. (13). For x_1 , we first compute its marginal discrete distribution:

$$\begin{aligned} p(x_1) &= \sum_{x_2, x_3, \dots, x_d} p(x_1, x_2, \dots, x_d) \\ &= \mathcal{G}(1, x_1, :) \sum_{x_2, x_3, \dots, x_d} \mathcal{G}(:, x_2, :) \cdots \mathcal{G}(:, x_d, 1) \\ &= \mathcal{G}(1, x_1, :) \mathbf{Q}_2. \end{aligned} \quad (17)$$

Then we sample index x_1 according to its distribution $p(x_1)$. In more detail, it first computes the cumulative distribution function (CDF) of $p(x_1)$, and then generates a random number using the uniform distribution $\mathcal{U}(0, 1)$. Next, we return the index of x_1 where the random number falls within the CDF. Iteratively, we sample x_2 index by its conditional distribution given x_1 :

$$\begin{aligned} p(x_2|x_1) &= \frac{p(x_2, x_1)}{p(x_1)} \\ &= \frac{\mathbf{P}_1 \mathcal{G}(:, x_2, :) \mathbf{Q}_3}{\mathbf{P}_1 \mathbf{Q}_2}. \end{aligned} \quad (18)$$

Similarly, the index x_2 can also be sampled by computing the CDF $p(x_2|x_1)$ and a uniform distribution. In summary, the k -th index x_k can be sampled by

$$\begin{aligned} p(x_k|x_{k-1}, \dots, x_2, x_1) &= \frac{p(x_k, x_{k-1}, \dots, x_1)}{p(x_1, x_2, \dots, x_{k-1})} \\ &= \frac{\mathbf{P}_{k-1} \mathcal{G}(:, x_k, :) \mathbf{Q}_{k+1}}{\mathbf{P}_{k-1} \mathbf{Q}_k}. \end{aligned} \quad (19)$$

7. Experiment Settings and Results

We implement our method using the PyTorch framework on a single NVIDIA V100 GPU. The implementation code for our methods can be found in the anonymous link <https://github.com/ynqiu/STEPS>.

7.1. Experiment Settings for Prompt Discovery

Datasets We evaluate the effectiveness of the learned prompt across six public datasets: MS COCO [17], Flickr30k [43], LAION [34], Celeb-A [18], TextVQA [37], and VizWiz [13]. For computational efficiency, we randomly sample 100 images from each dataset. These datasets cover diverse visual scenarios from natural scenes, ensuring comprehensive evaluation.

Model Settings For the prompt optimization model, we use OpenCLIP ViT-H/14 pre-trained on LAION-2B, which aligns with the text encoder architecture in Stable Diffusion (SD) v2, ensuring consistent semantic representation during optimization. All generations use a fixed random seed for reproducibility.

Baseline Settings

- PEZ [41]: Implementation follows the official repository with its default configuration for reproducibility.
- MMA [42]: Following their implementation with sensitive word filtering removed for fair comparison. Key hyperparameters include: coordinate-wise candidate size $k = 32$, batch size 1000, and maximum iterations 200.
- STEPS (Ours): We maintain comparable settings with baselines where possible. Core parameters include: candidate size $k = 32$, maximum batch size $M_{max} = 1000$, sampling size $M = 100$, and TT-ranks $R_j = 20$ for all $j \in \{1, \dots, d\}$. The memory budget l is set to 8, and the number of minimal-loss samples $n = 10$. All experiments run for 200 iterations.

Image Generation Settings After obtaining optimized prompts from all methods, we evaluate their effectiveness using SD v2. Generation parameters are kept at default values: guidance scale 7.5, inference steps 50, height and

Table 5. Running Time for Three Methods (in minutes)

Methods	MS COCO	Flick30k	Laion	Celeba	TextVQA	VizWiz
PEZ	1.62	1.57	1.53	1.59	1.57	1.61
GCG	14.43	13.16	13.09	13.15	13.10	13.03
Ours	<u>7.53</u>	<u>7.31</u>	<u>7.32</u>	<u>7.18</u>	<u>6.95</u>	<u>7.10</u>

width 512×512 . For each prompt, we generate five images with a fixed random seed for reproducibility.

Evaluation Settings For image evaluation, we generate five images for each optimized prompt and compute their cosine similarities with the target image using OpenCLIP-ViT/G as the reference model, which was not involved in the optimization process. The reported performance metrics in our paper represent the average cosine similarity scores across these five generations.

Computational Time Table 5 presents the average runtime (in minutes) for three methods with prompt lengths equal to 5 when learning a single prompt across different datasets. STEPS is faster compared to GCG, primarily due to its early stopping criterion. Empirical results indicate that STEPS typically converges within 60 iterations. Even without the early stopping mechanism, it requires approximately 23 minutes to complete the full 200 iterations.

7.2. Experiment Settings for Prompt Transferability

Cross-model Transfer Settings To evaluate prompt transferability, we test prompts optimized for SD v2 on SD XL v1.0. The SD XL v1.0 generation parameters are kept at default values: guidance scale 9.0, inference steps 30, height and width 1024×1024 . For each prompt, we generate five images with fixed random seeds and report the average cosine similarity scores computed using OpenCLIP-ViT/G as the reference model.

7.3. Experiment Settings and Results for NSFW Prompt Optimization

Datasets We utilize the Inappropriate Image Prompts (I2P) dataset from the Safe Latent Diffusion (SLD) [33], which contains real user prompts known to produce inappropriate content in text-to-image models. Specifically, we focus on the nudity category and further filter prompts with a nudity percentage of $\geq 70\%$, resulting in a relatively harder test set of 61 prompts.

Model Settings We employ a white-box/black-box evaluation framework using multiple diffusion models:

- White-box model: We employ SD v1.5 for image generation using the optimized prompts.
- Black-box models: SD v2 and SLD for transfer evaluation. Notably, SLD is a specialized version of Stable

Diffusion that has undergone safety fine-tuning to prevent inappropriate content generation through content filtering and model unlearning techniques.

The model parameters for SD v1.5 and v2 follow our previous settings. For SLD, we set the safety level to Medium for a comprehensive evaluation of safety measures.

Baseline Settings All the baseline methods are related to the removal of sensitive words set. In our experiment, we follow the sensitive words list as [42]. The sensitive word set includes {sexual, nude, nudity, sex, 18+, naked, nsfw, porn, dick, vagina, naked child, explicit content, uncensored, fuck, nipples, visible nipples, breast, areola, ak, na, ke, nud}.

- Genetic [45]: Following their genetic optimization framework, we preprocess the target prompt by removing sensitive words. For prompts with a length of less than 20 tokens after filtering, we augment them to reach 20 tokens. For prompts longer than 20 tokens, we add 5 additional learnable tokens. These augmented tokens are optimized through their genetic algorithm to maximize semantic alignment with the target prompt. For a fair comparison, we let the length of the learnable prompt for all methods be 20.
- MMA [42]: Following their implementation and default settings. Key hyperparameters include coordinate-wise candidate size $k = 256$, batch size 512, and maximum iterations 500.
- STEPS (Ours): Key parameters for STEPS include: candidate size $k = 128$, maximum sampling size $M_{max} = 10000$, sampling size $M = 100$, and TT-ranks $R_j = 20$ for all $j \in \{1, \dots, d\}$. The memory budget l is set to 8, and the number of minimal-loss samples $n = 10$. All experiments run for 200 iterations.

Evaluation Settings Our evaluation protocol involves three steps:

1. For each target prompt, we learn three adversarial candidate prompts using the text encoder from SD v1.5.
2. We sample three images using each adversarial candidate prompt using Diffusion Models (DMs) including SD v1.5, SD v2, and SLD.
3. An attack is considered successful if any one of the three candidate prompts generates inappropriate content. The attack success rate (ASR) is then calculated as the proportion of such successful prompts across all target prompts.
4. We conduct five independent runs on steps 2 to 3 with different random seeds and report the mean ASR across all runs.

Evaluation Methods To comprehensively evaluate the inappropriate content in generated images, we employ three detection methods:

Table 6. Notations and their corresponding descriptions

Notations	Descriptions
\mathcal{Y}	A d -order loss landscape tensor.
\mathcal{G}_j	The j -th core tensor in TT decomposition of probability tensor.
$\mathcal{G}_j(i)$	The i -th slice matrix of the j -th core tensor, where $\mathcal{G}_j(i) \in \mathbb{R}^{r_{j-1} \times r_j}$.
\oplus	Concatenation operator for combining core tensors along the second mode.
\mathbf{x}	A text prompt sequence consisting of d tokens.
\mathbf{e}_j	One-hot vector representation of the j -th token in the prompt.
\mathcal{V}_j	Vocabulary set containing candidate tokens for the j -th position.
$ \mathcal{V}_j $	Size of the vocabulary set for the j -th position.
\mathcal{X}	Complete prompt configuration space formed by the Cartesian product of vocabulary sets \mathcal{V}_j .
\boxtimes	Cartesian product operator between two sets.
\cup	Union operator for combining two sets.
\mathbb{P}_θ^t	Probability tensor at iteration t with parameters θ over the prompt configuration space.
r_j	The j -th TT-rank in TT decomposition
k	Number of tokens selected based on gradient information at each iteration.
l	Number of tokens sampled from previous iterations.

- NudeNet [3]: An open-source neural network-based nudity detection approach that provides binary classification and confidence scores. In this paper, we set the threshold to be 0.45 as the default.
- Q16 [31]: A CLIP-based inappropriate content detector that leverages prompt-tuning and pre-trained vision-language models to identify potentially inappropriate content including violence, misogyny, and other offensive materials, going beyond simple nudity detection.
- MHSC [27]: A comprehensive multi-headed safety classifier specifically designed to detect multiple categories of unsafe content, including sexually explicit, violent, disturbing, hateful, and political images.

Experiment Results on NSFW Prompt Optimization

We provide visualizations of successful attacks (both prompts and corresponding synthesis) identified by NudeNet in the end of supplementary material. **This content may contain some sensitive or disturbing images and**

text.

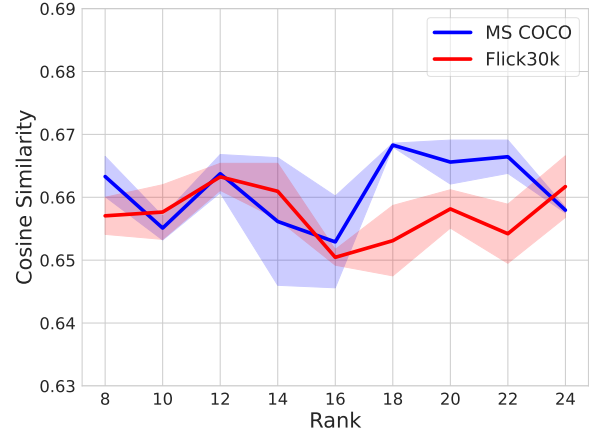

Figure 6. Cosine similarity across different TT ranks on COCO and Flick30k datasets.

7.4. Effectiveness of TT Rank

We conduct additional experiments to analyze the impact of TT-rank on model performance, as shown in Figure 6. Results from three independent runs demonstrate relatively stable performance across different ranks (from 8 to 24) on both MS COCO and Flick30k datasets. The cosine similarity scores consistently maintained in the range of [0.65, 0.67]. The solid lines represent mean performance while the shaded areas indicate the standard deviation across three runs with different random seeds. This empirical evidence suggests that our method is robust to rank selection, and moderate rank values are sufficient for effective prompt optimization without incurring unnecessary computational overhead.

Figure 7. Convergence comparison between our sequential probability tensor estimation and MMA (using coordinate-wise GCG [46]) on MS COCO and Flick30k datasets.

7.5. Convergence Results

To evaluate optimization dynamics, we compare our method with MMA, which adopts the GCG algorithm [46], on MS COCO and Flick30k datasets, as shown in Figure 7. Both approaches exhibit similar convergence patterns in the

early stages. However, as predicted by Introduction section, MMA’s adoption of coordinate-wise optimization strategy leads to earlier convergence to local optima. In contrast, our sequential probability tensor estimation approach demonstrates more stable optimization behavior and achieves better final performance.

8. Detailed Descriptions for Notations

For clarity and completeness, we summarize the key notations used throughout this paper in Table 6. These include tensor operations, prompt representations, and probability-related symbols essential to our framework.

The following table presents a comparison of prompts and their corresponding synthesis from the proposed STEPS and MMA approaches generated by SD v1.5. For clarity and space efficiency, we selectively visualize the image cases where the prompt successfully bypassed NudeNet. **Note that the following content (both text and images) may be disturbing to some readers.**
