## A. Effect on In-Domain Test Samples

In the main text, we apply VICT when a distribution shift occurs at test time. It is interesting to ask whether VICT works when the training and test distributions are the same. To study this, we perform VICT on clean test images for each task. As shown in Table 1, we observe no further performance gains or slight performance degradations compared with the Painter baseline. Since the Painter model has been well pre-trained on clean images, further applying VICT cannot extract additional information from data belonging to the training distribution and might instead lead to slight overfitting in some cases. In practice, one may rely on prior domain knowledge about the deployed environment to determine whether to apply VICT. Even if such knowledge is unavailable, in most cases, VICT does not hurt or only slightly hurts the original performance, but can significantly improve on many new distributions.

## B. Results on More Baselines and Tasks

In the main text, we mainly consider Painter as our baseline. To further demonstrate the generalizability of our method,

we apply VICT to another VICL baseline, *i.e.*, MAE-VQGAN [1]. Besides, we also apply VICT to more unseen tasks, including surface normal estimation on Taskonomy [5], foreground segmentation on DUTS [4], image deblurring on GoPro [3], and colorization on ImageNet [2]. We randomly sample 1000 images from their respective test or validation sets for evaluation. We sweep the learning rate for different tasks and train each test sample for 100 steps. As shown in Table 2, VICT consistently outperforms each baseline on different tasks by clear margins.

## C. Results on Other Severity Levels

Table 3-6 present the results on the other four corruption levels. In all experiments, we perform VICT using the same hyper-parameters as described in Section 4.1 in the main text without specialized tuning, except that we train each test sample for 20 steps (instead of 60, for faster experiments). Note that using the same hyper-parameters across different corruptions and levels can be sub-optimal. Nevertheless, VICT outperforms Painter regardless of settings, tasks, and corruption levels.

Table 3. System-level comparison on six representative vision tasks across 15 corruptions. Results are on corruption level 1.
