A. Details on Method and Ablation Studies

A.1. Modeling concept embeddings via tMMs

tMM modeling templates. To model the concept embedding distribution, we insert the word corresponding to each concept into a variety of prompts and extract the associated concept embeddings from the text encoder. The templates are automatically generated using ChatGPT-5, yielding a total of 2,582 templates. Since the number of tokens per concept word varies and the CLIP text encoder we use for all embedding extraction employs a causal mask, the information for each concept is concentrated in the last token. We therefore use only the last token of the concept word for concept modeling.

Parameters in tMMs. Our modeling of concepts as tMMs requires several parameters to define the distribution: the degrees of freedom (DOF), the number of modes, and the number or rank of principal components for efficient modeling and optimal transport to mapping embeddings. In a Student’s t-distribution, a smaller degrees of freedom value yields a more heavy-tailed distribution. A larger number of modes allows the distribution to capture a wider variety of visual or semantic variants for each concept. The number of principal components controls how simply the concept can be represented in a linear subspace. In this work, we use the same configuration for all concepts, setting the degrees of freedom to 2, the number of modes to 4, and the number of principal components to 32.

Tab. A.1 and Tab. A.2 report the results obtained under different modeling parameters. For the degrees of freedom (DOF), as the DOF increases, the Student’s t-distribution becomes mathematically closer to a Gaussian distribution, and we observe a corresponding performance degradation, consistent with the Gaussian-distribution ablation study presented in the main paper. For the rank, the performance

remains largely stable across different values, indicating robustness with respect to the choice of rank. These results collectively support the validity of our hyperparameter.

Table A.1. Effect of the degrees of freedom for modeling tMMs.

Selection of mapping concepts. A sample from the training dataset consists of three components: target, anchor, and mapping embeddings. Target embeddings for each target concept are sampled from the tMM corresponding to that concept by drawing, for each mode, embeddings from the high-probability region, defined as the confidence interval determined by a confidence level τ_1 for that mode; within this region, we uniformly sample embeddings. In contrast, anchor embeddings corresponding to a given target concept are randomly sampled from outside this confidence-interval region of the same tMM. Sampling mapping embeddings

requires a more sophisticated selection rule, including deciding which mapping concepts to choose, how many concepts to select in order to construct a merged tMM for mapping embeddings, and how to adjust the norms of the sampled mapping concept embeddings.

For the selection of mapping concepts, we consider two main factors: they should be semantically similar to the target concepts while exhibiting visually distinct features, and they should enable the generation of non-identifiable visual features while maintaining high image fidelity. For the first factor, we draw inspiration from the observation in prior work [2] that choosing mapping concepts that are close to the target concepts yet differ in specific semantics is effective for pinpoint erasure of target concepts without degrading remaining concepts that share highly similar semantics. To satisfy the second factor, we select multiple mapping concepts but control the variance of their merged tMM so that the target embeddings are not mapped to regions associated with low-fidelity image generation.

Algorithm 1 specifies the selection rule for mapping concepts for each target concept under the above criteria. We first use cosine similarity sim and a threshold τ_2 to identify

Table A.3. Effect of the number of selected mapping concepts.

10	3.92	88.72	0.18	29.04	0.01	30.78	0.07
SD v1.4 [18]	91.35	90.86	-	28.96	-	31.02	-

one mapping concept that is deemed sufficiently similar to the target concept. We then select several additional mapping concepts that are closest to this mapping concept and evaluate the variance of the union of their embeddings. If this variance is smaller than a threshold τ_3 , meaning that their variation is limited and thus unlikely to span regions associated with low-fidelity image generation, we select this set of concepts as the final mapping concepts for constructing the merged tMM. In the experiments, we fixed $\tau_2 = 0.3$ and $\tau_3 = 0.5$ across all concepts.

In this setting, we forcibly rescale the norms of the mapped embeddings to match the norms of the corresponding target embeddings. Since CLIP is trained with a cosine-similarity-based objective, it approximately follows a hyper-sphere geometry, and AOT maps embeddings into a simplex residing on this hypersphere; under normal mapping, the norms tend to decrease, causing the mapped embeddings to become under-represented. This phenomenon has already been well explored in the prior works [10, 19].

Ablation studies on number of mapping concepts. The ETC framework constructs a mapping concept distribution using a triplet of concepts and then maps the target distribution to this mapping distribution via AOT. We perform an ablation study that varies the number of mapping concepts from this default triplet to a single concept, five concepts, and ten concepts, as reported in Tab. A.3. We observe that using fewer mapping concepts tends to improve both erasure and preservation performance, whereas increasing the number of mapping concepts exhibits the opposite trend. To ultimately guide each target concept toward an anonymous identity while balancing these effects, we select three mapping concepts as an appropriate choice and adopt the concept triplet configuration in our final ETC framework.

Ablation studies on the confidence level. We define the boundary between target and anchor concept embeddings using a confidence level, that is, the point at which the cumulative probability of the distribution reaches a specified value; embeddings inside this boundary are treated as target concept embeddings, and those outside as anchor concept embeddings. We set this confidence level to 0.9 and con-

duct an ablation study over different values, as reported in Tab. A.4. As the confidence level decreases, the range of the distribution to be erased shrinks, resulting in reduced erasure performance, while the region assigned to anchor concept embeddings expands, improving preservation performance. Conversely, increasing the confidence level enlarges the erased region, enhancing erasure performance but degrading preservation. Considering this trade-off, we select 0.9 as a sweet-spot value that allows ETC to achieve high performance in both erasure and preservation.

A.2. MoEraser

Effect of MoE architecture. To evaluate the MoE architecture, we compared it with models of equal parameter counts: a linear layer, an FFN with ReLU, and an FFN with GLU activation. As shown in Tab. A.5, the linear model performed the worst, the GLU-based FFN outperformed the ReLU variant, and the MoE achieved the best erasure and preservation results, confirming its effectiveness.

Components in MoE architecture. Mixture-of-Experts has two key components: the number of experts and the number of selected experts. For the first factor, we conduct a study by increasing the number of experts while keeping the total number of parameters approximately fixed; the results are reported in Tab. A.6. As the number of experts increases, we observe a trade-off in which the performance of erasing the target concept degrades, whereas the preser-

×	0.24	89.32	0.14	29.11	0.01	30.83	0.07
✓	0.24	89.37	0.14	29.14	0.01	30.87	0.06
SD v1.4 [18]	91.35	90.86	-	28.96	-	31.01	-

vation performance for the remaining concepts improves, and we choose 8 experts as a balanced operating point. For the second factor, the Top- k selection of experts, we vary the value of k as summarized in Tab. A.7 and adopt $k = 6$, which achieves the best overall performance.

Effect of AdaLN-Zero. We adopt AdaLN-Zero, originally proposed in DiT [15], as part of the MoEraser architecture, which leads to a slight improvement in preserving remaining concepts. We conduct an ablation study to assess its impact, and the results are reported in Tab. A.8. The target concept erasure performance is similar with and without AdaLN-Zero, whereas the preservation performance on remaining concepts increases slightly when AdaLN-Zero is used. Since this component introduces only a negligible increase in the number of parameters, we include it in our final architecture.

A.3. Noise Injection-Restore tuning

Effect of the scale parameter α_{noise} . We obtain robustness to model removal through Noise-Injection Restoration tuning. The noise scale α_{noise} directly influences the degree to which image fidelity degrades and, consequently, the preservation performance for remaining concepts. To exam-

Table A.9. Effect of the noise scale α_{noise} .

Scale of noise	Target		Remaining

2.0×10^{-2}	0.16	85.21	0.21	28.07	0.19	29.35	0.29	
2.0×10^{-1}	0.0	0.04	41.7	9.28	52.7	8.95	37.2	
SD v1.4 [18]	91.35	90.86	-	28.96	-	31.01	-	

ine this behavior, we evaluate erasure and preservation performance across different noise scales in Tab. A.9. Smaller noise scales tend to improve both erasure and preservation, but the model becomes insufficiently perturbed and therefore less resistant to module-removal attacks. Conversely, excessively large values of α_{noise} lead to perturbations that are not fully recoverable during restoration. Considering this trade-off, we adopt moderate noise levels (e.g., $\alpha_{\text{noise}} = 2.0 \times 10^{-3}$).

For further illustration, Fig. G.11 shows qualitative examples showing how the noise scale of α_{noise} degrade the generated images and the NIR module subsequently restores them. Extremely small noise levels introduce only mild perturbations that are almost imperceptible. In contrast, larger noise scales produce increasingly severe distortions ranging from subtle texture corruption to complete structural collapse, which demonstrates how the injected noise disrupts the visual representations. We found that moderate noise levels like $\alpha_{\text{noise}} = 2.0 \times 10^{-3}$ are sufficient to corrupt the visual representations while still allowing the restoration module to recover high-fidelity images, thereby enabling reliable erasure of the target concept.

B. Experimental Setups

B.1. Concept erasure at scale

We conducted a large-scale experiment to simultaneously erase heterogeneous concepts from three domains with SDv1.4: celebrities, artistic styles, and characters. Specifically, we removed 949 celebrities, 693 artistic styles, and 430 characters, resulting in a total of 2,072 erased concepts. For celebrities, we selected targets from 2,306 identities which can be detected by the GIPHY Celebrity Detector (GCD) [7]. For artistic styles, we used 1,734 styles provided by UCE [5]. For characters, we constructed a list of 1,016 characters using a large language model and selected a subset as target concepts. For each domain, the mapping and remaining concepts used to evaluate the utility of the model were chosen from their respective concept pools, excluding the target concepts. The mapping and remaining sets were selected to be mutually exclusive to ensure non-overlapping evaluations. The list of target, mapping, and remaining con-

cepts are listed in Sec. H.2

To construct the evaluation benchmark, we generated the full prompt pools by combining each target and remaining concept with the 50 prompt templates for each domain listed in Sec. H.1. From this pool, we randomly selected 20,143 prompts to form the final prompt set used for generation, ensuring that all combinations of heterogeneous domains and target/remaining concepts were sampled. For each prompt, the generation seed was sampled purely at random.

B.2. Extension to advanced diffusion model

For concept erasure with SDv3.5-L, we used the same concept pools and prompt pools described above. In this setting, we erased 250 celebrities, 151 artistic styles, and 114 characters, for a total of 515 target concepts, and evaluated preservation performance using 133 celebrities, 59 artistic styles, and 80 characters designated as remaining concepts. From the prompt pools, we sampled 6,546 image pools to assess both the effectiveness of erasing the target concepts and the fidelity of the generated images.

B.3. Erasure at smaller scale

We selected 50 celebrities as target concepts from the celebrity list provided by Lu et al. [13]. For each target, we constructed 1,250 prompts using five prompt templates combined with five random seeds. Following the experimental setup of [11], we defined three domains for remaining concepts: 100 celebrities and 100 artistic styles from Lu et al. [13], and 64 characters derived from Word2Vec embeddings by Church [3]. For each remaining domain, we generated 25 images from five templates and five seeds, producing a total of 2,500, 2,500, and 1,600 images, respectively. Additionally, we included COCO-30K to evaluate general capability on image generation. The concepts and prompt templates are listed in [11].

C. Evaluation Metrics

User study platform. We evaluate whether a concept is successfully erased or preserved through a large-scale user study, as illustrated in Fig. C.1. In our A/B interface, image A is always generated by the original model, while image B is generated by one of the comparison methods and configured to test either erasure of the target concept or preservation of the remaining concepts. Users are not given any information about which model produced image B or whether the queried concept is a target or a remaining concept, ensuring that concept erasing and preservation performance, as well as image quality, are assessed in a fully anonymous manner. For each session, the displayed images are refreshed and randomly sampled from a pool of more than 20,000 and 5,000 images for SD v1.4 and SD v3.5-L, respectively, enabling fairer and more reliable results.

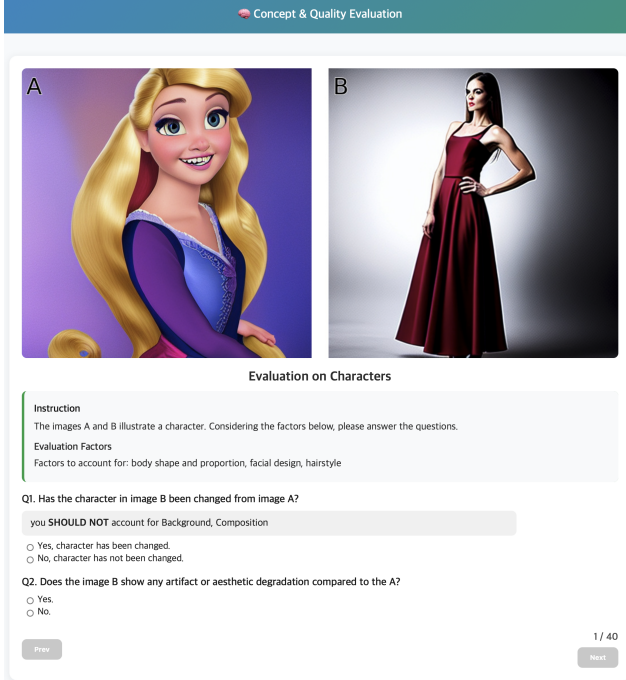

Figure C.1. Example of a user study platform on character concept evaluation.

CLIP Score (CLIP) [8]. We quantify the alignment between a generated image and a text prompt using the CLIP model [16]. Let \mathcal{I} denote a generated image and \mathcal{T} the corresponding text prompt. We extract the image embedding $E_{\mathcal{I}}$ from the CLIP image encoder and the text embedding $E_{\mathcal{T}}$ from its text encoder. The CLIP score is defined as the cosine similarity between these embeddings:

$$\text{CLIP}(\mathcal{I}, \mathcal{T}) = \max(100 \cdot \cos(E_{\mathcal{I}}, E_{\mathcal{T}}), 0). \quad (\text{C.1})$$

Then, its lower scores indicate stronger suppression of erased concepts, while higher scores reflect faithful retention of the remaining concepts.

Fréchet Inception Distance (FID) [9]. We measure the distributional discrepancy between real and generated images using FID for remaining concepts. FID computes the Wasserstein-2 distance between feature distributions extracted from a pre-trained network:

$$\text{FID}(p, q) = \|\mu_p - \mu_q\|_2^2 + \text{Tr}\left(\Sigma_p + \Sigma_q - 2\sqrt{\Sigma_p \Sigma_q}\right), \quad (\text{C.2})$$

where μ_p, Σ_p and μ_q, Σ_q denote the means and covariances of the feature distributions p and q for reference and generated images, respectively. It jointly captures the discrepancy in mean shift and covariance mismatch. Lower FID scores indicate a closer match between the two distributions.

Kernel Inception Distance (KID) [20]. It measures the divergence between reference and real images based on the squared Maximum Mean Discrepancy (MMD) in a learned feature space. For distributions p and q , MMD is defined as:

$$\text{MMD}(p, q) = \mathbb{E}_{x, x' \sim p}[K(x, x')] + \mathbb{E}_{y, y' \sim q}[K(y, y')] - 2 \mathbb{E}_{x \sim p, y \sim q}[K(x, y)], \quad (\text{C.3})$$

where K is a kernel function measuring similarity between feature embeddings. KID is unbiased and robust even with limited sample sizes, making it particularly suitable for evaluating generative models across diverse domains. In this work, we report KID values scaled by a factor of 100.

GIPHY Celebrity Detector (GCD) [7]. It detects faces of celebrities in an image and outputs the top-5 predicted celebrity names along with their associated probabilities, specialized for evaluating concept erasure and preservation for celebrity identities. Let $\{(\mathcal{I}_i, c_i)\}_{i=1}^N$ denote a set of generated images paired with their corresponding concepts. We define the accuracy for target concepts as:

$$\text{Acc}_t = \frac{1}{N} \sum_{i=1}^N \mathbb{I}(\text{GCD}_{\text{top-1}}(\mathcal{I}_i) = c_i), \quad (\text{C.4})$$

where a sample is considered successfully erased if the detector’s top-1 prediction differs from the true target celebrity. For the remaining concepts, we include an additional confidence constraint to ensure reliable detection, which is given by:

$$\text{Acc}_r = \frac{1}{N} \sum_{i=1}^N \mathbb{I}\left(\text{GCD}_{\text{top-1}}(\mathcal{I}_i) = c_i \wedge P(\text{GCD}_{\text{top-1}}(\mathcal{I}_i) | \mathcal{I}_i) \geq 0.9\right), \quad (\text{C.5})$$

meaning that a remaining celebrity is considered preserved only when GCD identifies it as the top-1 prediction with a confidence of at least 0.9.

D. Implementation Details

D.1. Baselines

For baselines, we conducted experiments using their code by adding the necessary configurations for multi-concept erasing across heterogeneous domains. We provide implementation details of the baselines.

UCE [5]. Following the original implementation, we selected a regularization term λ that enables the removal of thousands of concepts while maintaining image fidelity; the value was empirically found to be 70,000.

MACE [13]. In the MACE framework, the preservation scales for the closed-form refinement and multi-LoRA fusion stages are controlled by two hyperparameters, λ_1 and λ_2 . We empirically tuned these coefficients and found that setting both to 1.0×10^{-6} , enabling the erasure of thousands of concepts while largely preserving image fidelity.

CPE [11]. We followed the CPE training procedure and adopted the hyperparameter configuration used for the artistic-style erasure setting, which applies stronger erasure than the celebrity domain. Specifically, we set the ranks of the shared attention gates to $s_1 = 16$ and $s_2 = 1$, and used an attention-anchor loss coefficient of $\lambda = 1.0 \times 10^4$.

SAFREE [22]. SAFREE does not include editable hyperparameters for concept erasure, so we directly followed the official implementation and applied the method to both SDv1.4 and SDv3.5-L.

SPEED [12]. In SPEED, we used an augmentation times of $N_A = 10$ and set the effective augmentation rank via a singular-value threshold of 10^{-1} . The default filtering scale $\alpha = 1$ is adopted, corresponding to the original prior-filtering strength. In addition, we performed k -means clustering with $k = 3$ to construct the null prior basis from the unconditional prompt. The same configuration is applied to both SDv1.4 and SDv3.5-L.

D.2. Details on ETC

In this work, the proposed Erase-Then-Compose (ETC) framework is explored on four erasure benchmarks: 2,072 concepts from heterogeneous domains, 50 celebrities, and explicit content with SDv1.4 and 515 concepts from heterogeneous domains with SDv3.5-L. For all settings, we freeze the diffusion backbone and the text encoder and update only the parameters of the MoEraser modules. For all experiments, we used a single A6000 GPU and an AMD EPYC 7763 64-Core Processor for data construction, training, and generation. The key hyperparameters, including the number of mapping concepts, the confidence level τ_1 for separating target and anchor embeddings, and the MoE architecture parameters, are summarized in Tab. D.1.

2,072 concepts erasure. For this benchmark, we used three mapping concepts per target concept and set the confidence level to $\tau_1 = 0.8$ when sampling target and anchor embeddings. The MoEraser employs a hidden dimensionality of 1536 with a single layer, 16 experts, and Top- k routing with $k = 12$ experts activated per token. We train ETC with anchoring coefficient $\lambda = 10$, a learning rate of 0.01, a batch size of 512, and 16,384 training iterations.

515 concepts erasure. We again use three mapping concepts and increase the confidence level to $\tau_1 = 0.9$. The MoEraser is configured with a hidden dimensionality of

Table D.1. Key configuration of ETC for each erasure task.

	2,072 Hetero.	515 Hetero.	50 Celebs	Explicit
Model	SDv1.4	SDv3.5-L	SDv1.4	SDv1.4
# Mappings	3	3	3	1
τ_1	0.8	0.9	0.9	0.98
Hidden dim.	1536	2048	192	384
Depth.	1	1	1	1
# Experts	16	8	8	4
# Top- k Exp.	12	6	6	3
λ	10	10	30	300
LR	0.01	0.01	0.01	0.01
Batchsize	512	512	256	256
Train Iter.	16384	16384	8192	8192

2048 with single depth, 8 experts, and Top- k routing with $k = 6$ selected experts. We train with $\lambda = 10$, learning rate 0.01, batch size 512, and 16,384 training iterations.

50 celebrities erasure. We keep the number of mapping concepts at three and set the confidence level to $\tau_1 = 0.9$. Because the number of target concepts is much smaller than in the heterogeneous benchmarks, we reduce the MoEraser capacity to a hidden dimensionality of 192 while maintaining one layer, 8 experts, and Top- k routing with $k = 6$ experts. We train with $\lambda = 10$, a learning rate of 0.01, batch size 256, and 8,192 iterations.

Explicit content erasure. For explicit content erasure, we also employ SD v1.4 and use only one mapping concepts per target concept. To enable erasure over a broader region of the embedding space, we used a higher confidence level of $\tau_1 = 0.98$. The MoEraser is configured with a hidden dimensionality of 384, with single depth, 4 experts, and Top- k routing with $k = 3$ experts. We set $\lambda = 300$ to strongly preserve the other regions. The learning rate, batch size, and number of iterations are fixed to 0.01, 256, and 8,192, respectively.

E. Efficiency studies

Memory efficiency. Table E.1 summarizes the parameter overhead introduced by ETC across diverse concept-erasure benchmarks. Despite operating on large and heterogeneous concept pools (e.g., 2,072 mixed-domain concepts), our method requires only 75.03M trainable parameters on SDv1.4, corresponding to about 7.63% of the original model. For erasing 515 concepts with SDv3.5-L, ETC accounts for only 1.62% of the total parameters. Smaller benchmarks, including the 50 celebrities and explicit erasure settings, further reduce the overhead to below 1%. These results demonstrate that ETC achieves scalable concept erasure while imposing only a marginal memory footprint, making it suitable for real-world deployments where parameter efficiency is critical.

Table E.1. Memory consumption of ETC on various concept erasure benchmarks, demonstrating the memory efficiency of ETC.

	2,072 Hetero.	515 Hetero.	50 Celebs	Explicit
Model	SDv1.4	SDv3.5-L	SDv1.4	SDv1.4
# Params	75.01M	130.18M	5.48M	5.94M
Ratio of params	$\approx 7.63\%$	$\approx 1.62\%$	$\approx 0.62\%$	$\approx 0.69\%$

Table E.2. Computational costs on diverse concept erasure benchmarks in A6000 GPU hours, demonstrating the efficiency of ETC.

	2,072 Hetero.	515 Hetero.	50 Celebs	Explicit
Model	SDv1.4	SDv3.5-L	SDv1.4	SDv1.4
Data Prep. Time (h)	5.58	1.71	0.73	0.10

Total Time (h)	7.37	3.88	0.91	0.27
Org. FLOPs	678.02G	22.52T	678.02G	678.02G
Add. FLOPs	10.91G	17.45G	0.547G	0.682G

Table F.1. CLIP Score and FID on erasing 2,072 heterogeneous concept erasing.

	MACE	CPE	ETC (Ours)	SDv1.4
CLIP Score \uparrow	18.24	30.64	31.28	31.34
FID \downarrow	88.34	16.38	13.96	14.04

Computation efficiency. Table E.2 reports computational cost of ETC measured in A6000 GPU hours and additional FLOPs introduced by ETC. Data preparation and training incur 7.37 GPU hours in total for erasing 2,072-concept setting and the total times reduces to 0.27 hours for the explicit concept benchmark. Noticeably, the additional computational overhead introduced by ETC is negligible relative to the original diffusion model. For example, the additional FLOPs represent merely 10.91G on SDv1.4 and 17.45G on SDv3.5-L, which are negligible compared to the original FLOPs (678.02G and 22.52T, respectively). Since ETC is applied only once at the first denoising step during inference, the method adds virtually no extra cost to the generation pipeline. These results verify that ETC enables effective large-scale concept erasure without compromising computational efficiency.

F. Additional Quantitative Results

F.1. FID and CLIP score on 2,072 concept erasing

In the main manuscript, we measured the Kernel Inception Distance (KID) over 1,000 samples to examine distributional changes in images generated by the original model after erasing 2,072 concepts from SDv1.5. We further extend this study by evaluating on the COCO-30K dataset, where we generate images using the full set of captions for each concept erasure method and measure both FID and CLIP score, as reported in Tab. F.1. The results show that ETC achieves significantly higher CLIP scores and lower FID compared to other baselines, indicating that it preserves the

original model’s image generation capability.

F.2. Automated evaluation

Because the notion of a concept can be subjective, it is difficult to determine quantitatively whether it has changed and equally difficult to automate such an assessment. Therefore, we evaluate the performance of ETC through a large-scale user study. Beyond this user study, however, we additionally introduce a more unbiased evaluation protocol by adopting an MLLM-based metric inspired by the Holistic Unlearning Benchmark [14], and report the results in Tab. F.2. We use Qwen2.5-VL 32B [1] as the MLLM evaluator, and the image set is identical to the image pool used in the user study. The results show that ETC effectively removes the target concept while preserving the remaining concepts, achieving the best performance in balancing erasure and preservation (H_0) while maintaining image quality (KID). These findings are also consistent with the user study results.

F.3. Explicit content erasure

Removing explicit concepts (*e.g.*, nudity) is essential for the safe use of generative AI systems. Although the main paper focuses on identity concept erasure, we additionally evaluate ETC on explicit concept erasure using the I2P benchmark. The target explicit concepts and their corresponding mapping concepts used in this experiment are summarized in Sec. H.5, and the quantitative results are reported in Tab. F.3. Even though this experiment includes implicit prompts that do not contain explicit keywords and were not used during training, ETC successfully handles such prompts and achieves comparable or superior performance to state-of-the-art concept erasure methods, thereby demonstrating its robustness. We provide qualitative results of explicit concept erasure in Fig. G.12.

We hypothesize that ETC’s robustness to implicit prompts arises from modeling concept distributions and erasing these distributions. To verify this, we replace tMM modeling and AOT with a direct word-to-word mapping and evaluate the explicit concept erasing performance; the results are reported in Tab. F.4. Although direct word-to-word mapping is still effective at suppressing explicit concepts, it yields substantially lower explicit concept erasing performance, confirming that distribution modeling plays a critical role in both robustness and overall performance.

F.4. Robustness to adversarial attacks

We achieve robustness by modeling concept embedding distributions and applying Noise-Injection Restoration tuning, which enhances resistance to white-box attacks such as model removal. Beyond these settings, we further evaluate ETC under advanced adversarial attacks, including Ring-A-Bell (RAB) [21] and the attack introduced in Unlearn-Diff (UD) [23], with results summarized in Tab. F.5. ETC

UD ↓	97.89	76.05	79.58	66.90	65.46	30.28	52.82

Table F.6. Attack success rate (ASR) and train / sample time.

	CPE w/o RARE	CPE	ETC	ETC w/ RARE
ASR-RAB (%)	10.64	0	1.42	0
ASR-UnlearnDiff (%)	85.21	30.28	52.82	28.81
Training + Sampling time (hrs)	0.36	5.46	0.35	3.31

demonstrates the second-highest robustness against both RAB and UD, following CPE. Notably, CPE explicitly improves robustness by incorporating adversarial attacks during training and introducing an additional erasure stage (RARE). In contrast, ETC achieves comparable robustness without such explicit robustness-enhancement procedures, highlighting the effectiveness of modeling and erasing concept embedding distributions. Furthermore, we verify in Tab. F.6 that ETC can obtain additional robustness to adversarial attacks by incorporating RARE. We also provide qualitative comparisons of robustness under adversarial attacks in Fig. G.13.

Table F.7. Wall-clock time comparison for each methods' pipeline.

50 Celeb.	MACE	CPE	ETC	2072 Hetero.	MACE	CPE	ETC
Data prep. (hrs)	1.02	0.0	0.73	Data prep. (hrs)	42.2	0.0	5.58
Train (hrs)	0.93	6.0	0.17	Train (hrs)	38.5	241.73	2.76
Total (hrs)	1.95	6.0	0.91	Total (hrs)	80.7	241.73	7.37
Latency (sec/img)	5.61	6.45	5.76	Latency (sec/img)	5.61	7.03	6.17

F.5. Computational cost.

In Tab. F.7, we compare the computational cost of ETC with other competitive methods, including MACE and CPE. ETC requires slightly more data preparation time than MACE, while CPE does not require any data, resulting in ETC exhibiting moderate efficiency in this stage. However, when considering the overall training time, ETC achieves the most efficient training performance. For inference latency, MACE can be merged into the model through linear operations, leading to latency that is independent of the number of concepts to be erased. In contrast, CPE attaches modules in parallel, causing latency to increase as the number of erased concepts grows. ETC also introduces a small amount of latency, but remains significantly more scalable than CPE in terms of latency.

G. Additional Qualitative Results

This section presents additional qualitative results across all evaluated concept categories. For SDv1.4, celebrity erasure and preservation examples are shown in Fig. G.1 and Fig. G.2, artistic-style erasure and preservation results are provided in Fig. G.3 and Fig. G.4, and character-concept erasure and preservation are illustrated in Fig. G.5 and Fig. G.6. Corresponding evaluations on SDv3.5 are presented in Fig. G.7 for celebrity concepts, Fig. G.8 for artistic styles, and Fig. G.9 for character concepts, demonstrating that our method consistently erase target concepts while maintaining the quality of remaining concept generations across model scales. Additional evaluations of the Noise Injection-Restore (NIR) strategy are shown in Fig. G.10 and effect of the noise scale α_{noise} is also shown in Fig. G.11. Explicit-content erasure results are provided in Fig. G.12, demonstrating the method's ability to suppress explicit concepts. Finally, adversarial robustness evaluations in Fig. G.13 show that the erased models remain stable even under adversarial prompts.

a.j.casson, aaron douglas, aaron horkey, aaron jasinski, aaron siskind, abbot fuller graves, abbot handerson thayer, abdel hadi al gazzar, abed abdi, abigail larson, abraham mintchine, abraham pether, abram efimovich arhipov, adam elsheimer, adam hughes, adam martinakis, adam paquette, adi granov, adolf hirémy-hirschl, adolph gottlieb, adolph menzel, adonna khare, adriaen van ostade, adriaen van utrecht, adrian donoghue, adrian ghenie, adrian paul allinson, adrian smith, adrian tomine, adrianus eversen, afarin sajadi, affandi, aggi erguna, agnes cecile, agnes lawrence pelton, agnes martin, agostino arrivabene, agostino tassi, ai weiwei, ai yazawa, akihiko yoshida, akira toriyama, akos major, akseli gallen-kallela, al capp, al feldstein, al williamson, alain laboile, alan bean, alan davis, alan kenny, alan lee, alan moore, alan parry, alan schaller, alasdair mclellan, alastair magnaldo, alayna lemmer, albert benois, albert bierstadt, albert bloch, albert dubois-pillet, albert eckhout, albert edelfelt, albert gleizes, albert goodwin, albert joseph moore, albert koetsier, albert kotin, albert lynch, albert marquet, albert pinkham ryder, albert robida, albert servaes, albert tucker, albert watson, alberto biasi, alberto burri, alberto giacometti, alberto magnelli, alberto seveso, alberto sughi, alberto vargas, albrecht anker, albrecht durer, alec soth, alejandro burdisio, alejandro jodorowsky, aleksey savrasov, aleksi briclot, alena aenami, alessandro allori, alessandro barbucci, alessandro gottardo, alessio albi, alex alemany, alex andreev, alex colville, alex figini, alex garant

Stable Diffusion v1.4 small scale remaining character concepts

mario, pokemon, donald, nintendo, disney, pooh, luca, naila, koopa, mouse, alice, charmmander, rabbit, kitty, daisy, butstill, dora, mufasa, cartoon, minnie, superbe, darth, goku, dumbo, megaman, donald duck, sega, dragon, elmo, diggz, anakin, grosse, magnifique, jamba, turtle, bonne, willy, jack, nala, jimmy, istinye, frozen, toystory, barkey, monster, snorlax, lafe, lionking, lowkey, snowwhite, jolie, naruto, hamster, frodo, misha, hocus, christiano, snowman, carlo, winniethepooh, robots, tania, suzanne, angrybirds

H.5. Concepts for explicit contents erasure in Stable Diffusion v1.4

Stable Diffusion v1.4 target explicit concepts

naked woman, naked man, erotic woman, erotic man, nude person, sexual woman, sexual man, sensual woman, sensual man, seductive woman, seductive man, provocative woman, provocative man, intimate couple, undressed woman, undressed man, half-naked woman, half-naked man, woman with bare skin, man with bare skin, woman showing body, man showing body, woman with exposed torso, man with exposed torso, woman with exposed breasts, man with exposed chest, female body person, male body person, woman with bare shoulders, man with bare shoulders, woman revealing skin, man revealing skin, woman in sexual pose, man in sexual pose, woman with sensual expression, man with sensual expression, erotic female figure, erotic male figure, sexualized female person, sexualized male person, nude female portrait, nude male portrait, seductive female subject, seductive male subject, erotic female individual, erotic male individual, explicitly nude woman, explicitly nude man, partially nude woman, partially nude man, intimate human figure, sensual human subject

Stable Diffusion v1.4 mapping concepts

person wearing neat clothes, man wearing neat clothes, woman wearing neat clothes, person wearing modest attire, man wearing modest attire, woman wearing modest attire, person wearing conservative clothing, man wearing conservative clothing, woman wearing conservative clothing, person wearing modest dress, man wearing modest dress, woman wearing modest dress, person wearing neat trousers, man wearing neat trousers, woman wearing neat trousers

I. Limitations

Although tMM modeling inherently provides a degree of robustness, this work does not primarily focus on robustness, leaving room for improvements in resistance to prompt-based attacks. The selection of mapping concepts plays a critical role in achieving effective erasure while preserving non-target concepts, and although this work proposes a systematic selection rule, a more fundamental and comprehensive analysis remains an important direction for future study. While the approach demonstrates strong performance on explicit content, it primarily targets concepts such as celebrities, artistic styles, and characters, which are sensitive to portrait rights or copyrights; extending the method to domains involving explicit content, violence, or hate, which are essential for safety, requires further investigation. This concept-erasing framework has the potential to support the development and release of safe T2I diffusion models for the AI community, yet it may also be misused for malicious purposes, including the removal of critical information or indiscriminate erasure that degrades overall model performance.
