https://rich-text-to-image.github.io/

Figure 1. \textbf{Plain text (left image) vs. Rich text (right image).} Our method allows a user to describe an image using a rich text editor that supports various text attributes such as font family, size, color, and footnote. Given these text attributes extracted from rich text prompts, our method enables precise control of text-to-image synthesis regarding colors, styles, and object details compared to plain text.

Abstract

Plain text has become a prevalent interface for text-to-image synthesis. However, its limited customization options hinder users from accurately describing desired outputs. For example, plain text makes it hard to specify continuous quantities, such as the precise RGB color value or importance of each word. Furthermore, creating detailed text prompts for complex scenes is tedious for humans to write and challenging for text encoders to interpret. To address these challenges, we propose using a rich-text editor supporting formats such as font style, size, color, and footnote. We extract each word’s attributes from rich text to enable local style control, explicit token reweighting, precise color rendering, and detailed region synthesis. We achieve these capabilities through a region-based diffusion process. We first obtain each word’s region based on attention maps of a diffusion process using plain text. For each region, we enforce its text attributes by creating region-specific detailed prompts and applying region-specific guidance, and maintain its fidelity against plain-text generation through region-based injections. We present various examples of image generation from rich text and demonstrate that our method outperforms strong baselines with quantitative evaluations.

1. Introduction

The development of large-scale text-to-image generative models [52, 56, 54, 28] has propelled image generation to an unprecedented era. The great flexibility of these large-scale models further offers users powerful control of the generation through visual cues [4, 17, 77] and textual inputs [7, 19]. Without exception, existing studies use plain text encoded by a pretrained language model to guide the generation. However, in our daily life, it is rare to use only plain text when working on text-based tasks such as writing blogs or editing essays. Instead, a rich text editor [68, 71] is the more popular choice providing versatile formatting options for writing and editing text. In this paper, we seek to introduce accessible and precise textual control from rich text editors to text-to-image synthesis.

Rich text editors offer unique solutions for incorporating conditional information separate from the text. For example, using the font color, one can indicate an arbitrary color. In contrast, describing the precise color with plain text proves more challenging as general text encoders do
not understand RGB or Hex triplets, and many color names, such as ‘olive’ and ‘orange’, have ambiguous meanings. This font color information can be used to define the color of generated objects. For example, in Figure 1, a specific yellow can be selected to instruct the generation of a marble statue with that exact color.

Beyond providing precise color information, various font formats make it simple to augment the word-level information. For example, reweighting token influence [19] can be implemented using the font size, a task that is difficult to achieve with existing visual or textual interfaces. Rich text editors offer more options than font size – similar to how font style distinguishes the styles of individual text elements, we propose using it to capture the artistic style of specific regions. Another option is using footnotes to provide supplementary descriptions for selected words, simplifying the process of creating complex scenes.

But how can we use rich text? A straightforward implementation is to convert a rich-text prompt with detailed attributes into lengthy plain text and feed it directly into existing methods [54, 19, 7]. Unfortunately, these methods struggle to synthesize images corresponding to lengthy text prompts involving multiple objects with distinct visual attributes, as noted in a recent study [12]. They often mix styles and colors, applying a uniform style to the entire image. Furthermore, the lengthy prompt introduces extra difficulty for text encoders to interpret accurate information, making generating intricate details more demanding.

To address these challenges, our insight is to decompose a rich-text prompt into two components (1) a short plain-text prompt (without formatting) and (2) multiple region-specific prompts that include text attributes, as shown in Figure 2. First, we obtain the self- and cross-attention maps using a vanilla denoising process with the short plain-text prompt to associate each word with a specific region. Second, we create a prompt for each region using the attributes derived from rich-text prompt. For example, we use “mountain in the style of Ukiyo-e” as the prompt for the region corresponding to the word “mountain” with the attribute “font style: Ukiyo-e”. For RGB font colors that cannot be converted to the prompts, we iteratively update the region with alignment information between texts and regions in cross-attention maps for rich-text-to-image generation.

We demonstrate qualitatively and quantitatively that our method generates more precise color, distinct styles, and accurate details compared to plain text-based methods.

2. Related Work

Text-to-image models. Text-to-image systems aim to synthesize realistic images according to descriptions [82, 42]. Fueled by the large-scale text-image datasets [60, 9], various training and inference techniques [20, 62, 21, 22], and scalability [51], significant progress has been made in text-to-image generation using diffusion models [4, 51, 45, 56, 17], autoregressive models [52, 76, 11, 15], GANs [59, 28], and their hybrids [54]. Our work focuses on making these models more accessible and providing precise controls. In contrast to existing work that uses plain text, we use a rich text editor with various formatting options.

Controllable image synthesis with diffusion models. A wide range of image generation and editing applications are achieved through either fine-tuning pre-trained diffusion models [55, 32, 77, 3, 7, 30, 41, 35] or modifying the denoising process [43, 13, 19, 46, 5, 12, 2, 4, 26, 6, 58, 78, 9, 48, 48, 73, 16]. For example, Prompt-to-prompt [19] uses attention maps from the original prompt to guide the spatial structure of the target prompt. Although these methods can be applied to some rich-text-to-image applications, the results often fall short, as shown in Section 4. Concurrent with our work, Mixture-of-diffusion [26] and MultiDiffusion [6] propose merging multiple diffusion-denoising processes in different image regions through linear blending. Instead of relying on user-provided regions, we automatically compute regions of selected tokens using attention maps. Gradient [24] and Universal [5] guidance control the generation by optimizing the denoised generation at each step. We apply them to precise color generation by designing an objective on the target region to be optimized.

Attention in diffusion models. The attention mechanism has been used in various diffusion-based applications such as view synthesis [37, 66, 70], image editing [19, 12, 47, 46, 32], and video editing [38, 49, 10, 40]. We also leverage the spatial structure in self-attention maps and alignment information between texts and regions in cross-attention maps for rich-text-to-image generation.

Rich text modeling and application. Exploiting information beyond the intrinsic meanings of the texts has been previously studied [44, 63, 75, 34]. For example, visual information, such as underlining and bold type, have also been extracted for various document understanding tasks [75, 34]. To our knowledge, we are the first to leverage rich text information for text-to-image synthesis.

Image stylization and colorization. Style transfer [18, 81, 39] and Colorization [53, 64, 74, 33, 79, 80] for editing real images have also been extensively studied. In contrast, our work focuses on local style and precise color control for generating images from text-to-image models.
3. Rich Text to Image Generation

From writing messages on communication apps, designing websites [57], to collaboratively editing a document [36, 25], a rich text editor is often the primary interface to edit texts on digital devices. Nonetheless, only plain text has been used in text-to-image generation. To use formatting options in rich-text editors for more precise control over the black-box generation process [1], we first introduce a problem setting called rich-text-to-image generation. We then discuss our approach to this task.

3.1. Problem Setting

As shown in Figure 2, a rich text editor supports various formatting options, such as font styles, font size, color, and more. We leverage these text attributes as extra information to increase control of text-to-image generation. We interpret the rich-text prompt as JSON, where each text element consists of a span of tokens \( e_i \) (e.g., ‘church’) and attributes \( a_i \) describing the span (e.g., ‘color:#FF9900’). Note that some tokens \( e_i \) may not have any attributes. Using these annotated prompts, we explore four applications: 1) local style control using font style, 2) precise color control using font color, 3) detailed region description using footnotes, and 4) explicit token reweighting with font sizes.

Font style is used to apply a specific artistic style \( \alpha_s^e \), e.g., \( \alpha_s^e = \text{‘Ukiyo-e’} \), to the synthesis of the span of tokens \( e_i \). For instance, in Figure 1, we apply the Ukiyo-e painting style to the ocean waves and the style of Van Gogh to the sky, enabling the application of localized artistic styles. This task presents a unique challenge for existing text-to-image models, as there are limited training images featuring multiple artistic styles. Consequently, existing models tend to generate a uniform mixed style across the entire image rather than distinct local styles.

Font color indicates a specific color of the modified text span. Given the prompt “a red toy”, the existing text-to-image models generate toys in various shades of red, such as light red, crimson, or maroon. The color attribute provides a way for specifying a precise color in the RGB color space, denoted as \( \alpha_c^e \). For example, to generate a toy in fire brick red, one can change the font color to “a toy”, where the word “toy” is associated with the attribute \( \alpha_c^e = [178,34,34] \). However, as shown in the experiment section, the pretrained text encoder cannot interpret the RGB values and have difficulty understanding obscure color names, such as lime and orange.

Footnote provides supplementary explanations of the target span without hindering readability with lengthy sentences. Writing detailed descriptions of complex scenes is tedious work, and it inevitably creates lengthy prompts [29, 27]. Additionally, existing text-to-image models are prone to ignoring some objects when multiple objects are present [12], especially with long prompts. Moreover, excess tokens are discarded when the prompt’s length surpasses the text encoder’s maximum length, e.g., 77 tokens for CLIP models [50]. We aim to mitigate these issues using a footnote string \( \alpha_f^e \).

Font size can be employed to indicate the importance, quantity, or size of an object. We use a scalar \( \alpha_w^e \) to denote the weight of each token.
3.2. Method

To utilize rich text annotations, our method consists of two steps, as shown in Figure 2. First, we compute the spatial layouts of individual token spans. Second, we use a new region-based diffusion to render each region’s attributes into a globally coherent image.

**Step 1. Token maps for spatial layout.** Several works [65, 40, 4, 19, 12, 47, 67] have discovered that the attention maps in the self- and cross-attention layers of the diffusion UNet characterize the spatial layout of the generation. Therefore, we first use the plain text as the input to the diffusion model and collect self-attention maps of size $32 \times 32 \times 32 \times 32$ across different heads, layers, and time steps. We take the average across all the extracted maps and reshape the result into $1024 \times 1024$. Note that the value at $j$th row and $i$th column of the map indicates the probability of pixel $i$ attending to pixel $j$. We average the map with its transpose to convert it to a symmetric matrix. It is used as a similarity map to perform spectral clustering [61, 69] and obtain the binary segmentation maps $\hat{M}$ of size $K \times 32 \times 32$, where $K$ is the number of segments.

To associate each segment with a textual span, we also extract cross-attention maps for each token $w_j$:

$$m_j = \frac{\exp(s_j)}{\sum_k \exp(s_k)},$$

where $s_j$ is the attention score. We first interpolate each cross-attention map $m_j$ to the same resolution as $\hat{M}$ of $32 \times 32$. Similar to the processing steps of the self-attention maps, we compute the mean across heads, layers, and time steps to get the averaged map $\bar{m}_j$. We associate each segment with a texture span $e_i$ following Patashnik et al. [47]:

$$M_{e_i} = \{ \hat{M}_k \mid \hat{M}_k \cdot \bar{m}_j - \min(\bar{m}_j) \over \max(\bar{m}_j) - \min(\bar{m}_j) \} > \epsilon, \forall \{ \text{w}_j \in e_i \},$$

where $\epsilon$ is a hyperparameter that controls the labeling threshold, that is, the segment $\hat{M}_k$ is assigned to the span $e_i$ if the normalized attention score of any tokens in this span is higher than $\epsilon$. We associate the segments that are not assigned to any formatted spans with the unformatted tokens $e_U$. Finally, we obtain the token map in Figure 2 as below:

$$M_{e_i} = \frac{\sum \hat{M}_j \cdot \bar{m}_j}{\sum \hat{M}_j}$$

**Step 2. Region-based denoising and guidance.** As shown in Figure 2, given the text attributes and token maps, we divide the overall image synthesis into several region-based denoising and guidance processes to incorporate each attribute, similar to an ensemble of diffusion models [32, 6]. More specifically, given the span $e_i$, the region defined by its token map $M_{e_i}$, and the attribute $a_i$, the predicted noise $e_i$ for noised generation $X_t$ at time step $t$ is

$$e_i = \sum_i M_{e_i} \cdot \epsilon_{t, e_i} + \sum_i M_{e_i} \cdot D(X_t, f(e_i, a_i), t),$$

where $D$ is the pretrained diffusion model, and $f(e_i, a_i)$ is a plain text representation derived from text span $e_i$ and attributes $a_i$ using the following process:

1. Initially, we set $f(e_i, a_i) = e_i$.
2. If footnote $a_i^f$ is available, we set $f(e_i, a_i) = a_i^f$.
3. The style $a_i^s$ is appended if it exists. $f(e, a_i) = f(e, a_i) + \alpha^s$. 

4. The closest color name (string) of font color $\hat{a}_i^c$ is detected from a predefined set $C$. $f(e, a_i) = f(e, a_i) + f(e, a_i)$. For example, $\hat{a}_i^c = \text{‘brown’}$ for RGB color $a_i^c = [136, 68, 20]$.

We use $f(e, a)$ as the original plain text prompt of Step 1 for the unformatted tokens $e_U$. This helps us generate a coherent image, especially around region boundaries.

**Guidance.** By default, we use classifier-free guidance [23] for each region to better match the prompt $f(e, a)$. In addition, if the font color is specified, to exploit the RGB values information further, we apply gradient guidance [24, 14, 5] on the current clean image prediction:

$$\hat{x}_t = \frac{x_t - \sqrt{1 - \alpha_t} \epsilon_t}{\sqrt{1 - \alpha_t}}$$

where $x_t$ is the noisy image at time step $t$, and $\alpha_t$ is the coefficient defined by noise scheduling strategy [20]. Here, we compute an MSE loss $\mathcal{L}$ between the average color of $\hat{x}$ weighted by the *token map* $M_e$, and the RGB triplet $a_i^c$. The gradient is calculated below,

$$\frac{d\mathcal{L}}{dx_t} = \frac{d\| \sum_p (M_e \cdot \hat{x}_t) / \sum_p M_e - a_i^c \|^2_2}{dx_t}$$

where the summation is over all pixels $p$. We then update $x_t$ with the following equation:

$$x_t \leftarrow x_t - \lambda \cdot M_e \cdot \frac{d\mathcal{L}}{dx_t}$$

where $\lambda$ is a hyperparameter to control the strength of the guidance. We use $\lambda = 1$ unless denoted otherwise.

**Token reweighting with font size.** Last, to re-weight the impact of the token $e_U$ according to the font size $a_i^f$, we modify its cross-attention maps $m_j$. However, instead of applying direct multiplication as in Prompt-to-Prompt [19], where $\sum_j a_i^f m_j \neq 1$, we find that it is critical to preserve the probability property of $m_j$. We thus propose the following reweighting approach:

$$\hat{m}_j = \frac{a_i^f \exp(s_j)}{\sum_k a_i^f \exp(s_k)}$$

We can compute the token map (Equation 3) and predict the noise (Equation 4) with the reweighted attention map.

**Preserve the fidelity against plain-text generation.** Although our region-based method naturally maintains the layout, there is no guarantee that the details and shape of the objects are retained when no rich-text attributes or only the color is specified, as shown in Figure 12. To this end, we follow Plug-and-Play [67] to inject the self-attention maps and the residual features extracted from the plain-text generation process when $t > T_pnp$ to improve the structure fidelity. In addition, for the regions associated with the unformatted tokens $e_U$, stronger content preservation is desired. Therefore, at certain $t = T_{\text{blend}}$, we blend the noise $x_t^{\text{plain}}$ based on the plain text into these regions:

$$x_t \leftarrow M_{e_U} \cdot x_t^{\text{plain}} + (1 - M_{e_U}) \cdot x_t$$

4. **Experimental Results**

**Implementation details.** We use Stable Diffusion V1-5 [53] for our experiments. To create the token maps, we use the cross-attention layers in all blocks, excluding the first encoder and last decoder blocks, as the attention maps in these high-resolution layers are often noisy. We discard
A night sky filled with stars (1st Region: Van Gogh) above a turbulent sea with giant waves (2nd Region: Ukiyo-e).

The awe-inspiring sky and sea (1st Region: J.M.W. Turner) by a coast with flowers and grasses in spring (2nd Region: Monet).

Figure 5. **Qualitative comparison on style control.** We show images generated by Prompt-to-Prompt, InstructPix2Pix, and our method using prompts with multiple styles. Only our method can generate distinct styles for both regions.

Figure 6. **Quantitative evaluation of local style control.** We report the CLIP similarity between each stylized region and its region prompt. Our method achieves the best stylization.

the maps at the initial denoising steps with $T > 750$. We use $K = 15$, $\epsilon = 0.3$, $T_{\text{inp}} = 0.3$, $T_{\text{blend}} = 0.3$, and report the results averaged from three random seeds for all quantitative experiments. More details, such as the running time, can be found in Appendix B.

**Font style evaluation.** We compute CLIP scores \cite{radford2021learning} for each local region to evaluate the stylization quality. Specifically, we create prompts of two objects and styles. We create combinations using 7 popular styles and 10 objects, resulting in 420 prompts. For each generated image, we mask it by the token maps of each object and attach the masked output to a black background. Then, we compute the CLIP score using the region-specific prompt. For example, for the prompt “a lighthouse (Cyberpunk) among the turbulent waves (Ukiyo-e)”, the local CLIP score of the lighthouse region is measured by comparing its similarity with the prompt “lighthouse in the style of cyberpunk.” We refer to “lighthouse” as the first region and “waves” as the second region in this example.

**Font color evaluation.** To evaluate a method’s capacity to understand and generate a specific color, we divide colors into three categories. The Common color category contains 17 standard names, such as “red”, “yellow”, and “pink”. The HTML color names are selected from the web color names \footnote{https://simple.wikipedia.org/wiki/Web_color} used for website design, such as “sky blue”, “lime green”, and “violet purple”. The RGB color category contains 50 randomly sampled RGB triplets to be used as “color of RGB values $[128, 128, 128]$”. To create a complete
prompt, we use 12 objects exhibiting different colors, such as “flower”, “gem”, and “house”. This gives us a total of 1,200 prompts. We evaluate color accuracy by computing the mean L2 distance between the region and target RGB values. We also compute the minimal L2 distance as sometimes the object should contain other colors for fidelity, e.g., the “black tires” of a “yellow car”.

**Baselines.** For font color and style, we quantitatively compare our method with two strong baselines, Prompt-to-Prompt [19] and InstructPix2Pix [7]. When two instructions exist for each image in our font style experiments, we apply them in parallel (InstructPix2Pix-para) and sequential manners (InstructPix2Pix-seq). More details are in Appendix B. We also perform a human evaluation with these two methods in Appendix Table 1. For re-weighting token importance, we visually compare with Prompt-to-Prompt [19] and two heuristic methods, repeating and adding parentheses. For complex scene generation with footnotes, we also compare with Attend-and-Excite [12].

### 4.1. Quantitative Comparison

We report the local CLIP scores computed by a ViT-B/32 model in Figure 6. Our method achieves the best overall CLIP score compared to the two baselines. This demonstrates the advantage of our region-based diffusion method for localized stylization. To further understand the capacity of each model to generate multiple styles, we report the metric on each region. Prompt-to-Prompt and InstructPix2Pix-para achieve a decent score on the 1st Region, i.e., the region first occurs in the sentence. However, they often fail to fulfill the style in the 2nd Region. We conjecture that the Stable Diffusion model tends to generate a uniform style for the entire image, which can be attributed to single-style training images. Furthermore, InstructPix2Pix-seq performs the worst in 2nd Region. This is because the first instruction contains no information about the second region, and the
Ours: A pizza with pineapples, pepperonis, and mushrooms
Prompt-to-Prompt
A pizza with pineapples, pepperonis, and mushrooms, mushrooms, mushrooms, mushrooms, mushrooms
A pizza with pineapples, pepperonis, and (((((mushrooms)))))

Figure 9. **Qualitative comparison on token reweighting.** We show images generated by our method and Prompt-to-Prompt using token weight of 13 for ‘mushrooms’. Prompt-to-Prompt suffers from artifacts due to the large weight. Heuristic methods like repeating and parenthesis do not work well.

Figure 10. **Ablation of token maps.** Using solely cross-attention maps to create token maps leads to inaccurate segmentations, causing the background to be colored in an undesired way.

We show quantitative results of precise color generation in Figure 7. The distance of HTML color is generally the lowest for baseline methods, as they provide the most interpretable textual information for text encoders. This aligns with our expectation that the diffusion model can handle simple color names, whereas they struggle to handle the RGB triplet. Our rich-text-to-image generation method consistently improves on the three categories and two metrics over the baselines.

### 4.2. Visual Comparison

**Precise color generation.** We show qualitative comparison on precise color generation in Figure 4. InstructPix2Pix [7] is prone to create global color effects rather than accurate local control. For example, in the flower results, both the vase and background are changed to the target colors. Prompt-to-Prompt [19] provides more precise control over the target region. However, both Prompt-to-Prompt and InstructPix2Pix fail to generate precise colors. In contrast, our method can generate precise colors for all categories and prompts.

**Local style generation.** Figure 5 shows a visual comparison of local style generation. When applying InstructPix2Pix-seq, the style in the first instruction dominates the entire image and undermines the second region. Figure 13 in Appendix shows that this cannot be fully resolved using different hyperparameters of classifier-free guidance. Similar to our observation in the quantitative evaluation, our baselines tend to generate the image in a globally uniform style instead of distinct local styles for each region. In contrast, our method synthesizes the correct styles for both regions. One may suggest applying baselines with two stylization processes independently and composing the results using token maps. However, as shown in Figure 12 (Appendix), such methods generate artifacts on the region boundaries.

**Complex scene generation.** Figure 8 shows comparisons on complex scene generation. Attend-and-Excite [12] uses the tokens missing in the full-text generation result as input to fix the missing objects, like the coffee table and carpet in the living room example. However, it still fails to generate all the details correctly, e.g., the books, the painting, and the blanket. Prompt-to-Prompt [19] and InstructPix2Pix [7] can edit the painting accordingly, but many objects, like the colorful pillows and stuff on the table, are still missing. In contrast, our method faithfully synthesizes all these details described in the target region.

**Token importance control.** Figure 9 shows the qualitative comparison on token reweighting. When using a large weight for ‘mushroom,’ Prompt-to-Prompt generates clear artifacts as it modifies the attention probabilities to be unbounded and creates out-of-distribution intermediate features. Heuristic methods fail with adding more mushrooms, while our method generates more mushrooms and preserves the quality. More results of different font sizes and target tokens are shown in Figures 23 - 25 in Appendix.
Figure 11. **Our workflow.** (top left) A user begins with an initial plain-text prompt and wishes to refine the scene by specifying the color, details, and styles. (top center) Naively inputting the whole description in plain text does not work. (top right) InstructPix2Pix [7] fails to make accurate editing. (bottom) Our method supports precise refinement with region-constrained diffusion processes. Moreover, our framework can naturally be integrated into a rich text editor, enabling a tight, streamlined UI.

Figure 12. **Ablation of injection method.** We show images generated based on plain text and rich text with or without injection methods. Injecting features and noised samples help preserve the structure of the church and unformatted token regions.

**Interactive editing.** In Figure 11, we showcase a sample workflow to illustrate our method’s interactive strength and editing capacity over InstructPix2Pix [7].

### 4.3. Ablation Study

**Generating token maps solely from cross-attention.** The other straightforward way to create token maps is to use cross-attention maps directly. To ablate this, we first take the average of cross-attention maps across heads, layers, and time steps and then take the maximum across tokens. Finally, we apply softmax across all the spans to normalize the token maps. However, as shown by the example in Figure 10, since the prompt has no correspondence with the background, the token map of “shirt” also covers partial background regions. Note that simple thresholding is ineffective as some regions still have high values, e.g., the right shoulder. As a result, the target color bleeds into the background. Our methods obtain more accurate token maps and, consequently, more precise colorization.

**Ablation of the injection methods.** To demonstrate the effectiveness of our injection method, we compare image generation with and without it in Figure 12. In the font color example, we show that applying the injection effectively preserves the shape and details of the target church and the structure of the sunset in the background. In the footnote example, we show that the injection keeps the looking of the black door and the color of the floor.

### 5. Discussion and Limitations

In this paper, we have expanded the controllability of text-to-image models by incorporating rich-text attributes as the input. We have demonstrated the potential for generating images with local styles, precise colors, different token importance, and complex descriptions. Nevertheless, numerous formatting options remain unexplored, such as bold/italic, hyperlinks, spacing, and bullets/numbering. Also, there are multiple ways to use the same formatting options. For example, one can use font style to characterize the shape of the objects. We hope this paper encourages further exploration of integrating accessible daily interfaces into text-based generation tasks, even beyond images.

**Limitations.** As we use multiple diffusion processes and two-stage methods, our method can be multiple times slower than the original process. Also, our way to produce token maps relies on a thresholding parameter. More advanced segmentation methods like SAM [31] could be exploited to further improve the accuracy and robustness.

**Acknowledgment.** We thank Mia Tang, Aaron Hertzmann, Nupur Kumari, Gaurav Parmar, Ruihan Gao, and Aniruddha Mahapatra for their helpful discussion and paper reading. This work is partly supported by NSF grant No. IIS-239076, as well as NSF grants No. IIS-1910132 and IIS-2213335.
