Single Image Defocus Deblurring via Implicit Neural Inverse Kernels
(Supplemental Material)

1. Proof of Proposition 1

Consider an image space \( \mathbb{R}^{H \times W} \). For a PSF \( k \in \mathbb{R}^{H \times W} \) with \( H \ll H_0 \) and \( W \ll W_0 \), its inverse kernel \( k^\dagger \) is defined in the frequency domain as follows: for 
\[
0 \leq \omega_x < H_0, 0 \leq \omega_y < W_0, 
\]
\[
\mathcal{F}(k^\dagger)[\omega_x, \omega_y] = \left\{ \begin{array}{ll} 
\frac{1}{\mathcal{F}(k)[\omega_x, \omega_y]}, & \text{if } |\mathcal{F}(k)[\omega_x, \omega_y]| \neq 0; \\
0, & \text{otherwise}.
\end{array} \right.
\]
(1)

Consider the standard expansion-based dyadic upsampling operator \( U_s := \uparrow_s \), where the operator \( \uparrow_s : \mathbb{R}^{H \times W} \rightarrow \mathbb{R}^{sH \times sW} \) can be defined in the Fourier domain as follows:
\[
(k \uparrow_s)[\omega_x, \omega_y] = \left\{ \begin{array}{ll} 
\frac{k[\omega_x/s, \omega_y/s]}{s}, & \text{if } \frac{\omega_x}{s}, \frac{\omega_y}{s} \in \mathbb{Z}; \\
0, & \text{otherwise}.
\end{array} \right.
\]
(2)

In the remaining discussion, any index \([\omega_1, \omega_2]\) outside the range \([0, H_0 - 1] \times [0, W_0 - 1]\) is defined as \([\omega_1 \mod H_0, \omega_2 \mod W_0]\). Then, we have
\[
\mathcal{F}(k^\dagger)[\omega_x, \omega_y] = \mathcal{F}(k)[s\omega_x, s\omega_y].
\]
(3)

By the definition of inverse kernel, we have then
\[
\mathcal{F}((k^\dagger)^\dagger)[\omega_x, \omega_y] = \left\{ \begin{array}{ll} 
\frac{1}{\mathcal{F}(k)[s\omega_x, s\omega_y]}, & \text{if } |\mathcal{F}(k)[s\omega_x, s\omega_y]| \neq 0; \\
0, & \text{otherwise}.
\end{array} \right.
\]
(4)

Thus, we have
\[
(k \uparrow_s)^\dagger = (k^\dagger)^\dagger \uparrow_s.
\]
(5)

That is, the inverse kernel and the upsampling operator are commutative. Suppose that \( k^\dagger \) can be expressed as a linear combination over a set of atoms \( V = \{v_n\}_{n=1}^N \):
\[
k^\dagger = \sum_{n=1}^N w_n \cdot v_n,
\]
(6)

Then, we have
\[
(k \uparrow_s)^\dagger = (k^\dagger)^\dagger \uparrow_s = (\sum_{n=1}^N w_n \cdot v_n)^\dagger \uparrow_s = \sum_{n=1}^N w_n \cdot (v_n \uparrow_s)^\dagger.
\]
(7)

Remark 1. For interpolation-based upsampling operators, they usually can be expressed as
\[
U_s(k) = (k \uparrow_s) * h_s,
\]
for some low-pass filter \( h_s \) whose size is related to \( s \). For instance, \( h_s = \left[ \frac{1}{2}, 1, \frac{1}{2} \right] \) for 1D linear interpolation on \( s = 2 \).

Based on (5) and that \((a * b)^\dagger = a^\dagger * b^\dagger\), we have a generalized commutativity between inverse kernel and upsampling:
\[
(U_s(k))^\dagger = (k \uparrow_s)^\dagger * h_s^\dagger = ((k^\dagger)^\dagger \uparrow_s) * h_s^\dagger.
\]
(9)

As a result, in analog to (7), we have a generalized span:
\[
(U_s(k)) \uparrow_s = \sum_{n=1}^N w_n \cdot (v_n \uparrow_s h_s^\dagger).
\]
(10)
Such a generalized form is implicitly implemented in our INR-based model.

2. Additional Analysis

2.1. Influence of Atom Size and Atom Number

We investigate the impact of two main hyper-parameters, maximum atom size and atom number, in our INR-based model, by fixing one and varying the other. Concretely, we vary the maximum atom size to 7, 9, 11, 13, 15, 17, 19, respectively, with a fixed atom number of 10, and we vary the atom number to 2, 4, 6, 8, 10, 12, 14, 16, respectively, with a fixed maximum atom size of 15×15. The results plotted in Fig. 1 show that (a) when the atom size or atom number is too small, the performance of our INIKNet decreases noticeably, which is probably caused by under-fitting; (b) when setting the two hyper-parameters to larger values than the ones used in our experiments, the performance of INIKNet even has certain increase in some cases; (c) when the atom number is set too large, INIKNet performs slightly worse, probably due to overfitting; and (d) within a reasonable range of the hyper-parameters, INIKNet performs stably well.

2.2. Deblurring via INR Atoms vs. Non-INR Atoms

See Fig. 2 for some deblurred images on the CUHK dataset using INIKNet and its non-INR version respectively.
Figure 1: PSNR w.r.t. max atom size and atom number.

Figure 2: Deblurred image using INR-based model vs. non-INR model on CUHK dataset (without ground-truths). Zoom in for better views.

Leveraging INR-based inverse kernel atoms, INIKNet can recover cleaner textures with fewer artifacts.

2.3. Polar vs. Grid Coordinates in INR

As mentioned in Section 4.2 [Details of Key Modules] of our main paper, using polar coordinates instead of grid coordinates as input is one difference for INR from many existing works and can lead to some performance improvement (though not our main contribution). See Table 1 for their results for comparison.

2.4. Performance Comparison to MIMOUNet

MIMOUNet [1] is a popular multi-scale NN for dynamic scene deblurring which employs asymmetric feature fusion to directly aggregate features of different scales. Table 2 presents the results of MIMOUNet trained on DPDD under the same training setting as ours. The MIMOUNet shows close performance to our INIKNet, but using a much larger model. In addition, its generalization performance on RealDOF and RTF is not as good as that of INIKNet, particularly that the PSNR gap is more than 0.8dB on RTF. These results again demonstrate the effectiveness of our approach.

3. Additional Qualitative Results

In addition to those in the main paper, we provide extensive visual comparisons in Fig. 3, 4, 6, 5, 7, 8. When our INIKNet model is trained on DPDD, it not only performs well on the corresponding test split (see Fig. 3), but also shows superior generalization performance on RealDOF (see Fig. 4) and CUHK (see Fig. 5) both of which have a large domain gap against DPDD. Same thing happens when training on LFDOF (see Fig. 6, 7, 8). Under some extreme situations with severe blur, most methods fail while ours still work. Note that although the DRBNet trained on LFDOF achieves comparable performance to our INIKNet on LFDOF, its generalization performance to unseen patterns on CUHK is not as good as that of INIKNet (see Fig. 7, 8). These additional results further demonstrate the superiority of our proposed approach.
