1. Experiment Settings for Compared Methods

In this section, we describe the experimental setup for the five existing adaptive compression methods. Yang *et al.* [7] perform only latent refinement without tuning decoders, which corresponds to the first stage of our approach. Lam *et al.* [4] update the bias parameters in the convolutional layers of the decoder after latent refinement. These parameters are optimized solely for distortion and are converted to 64-bit floating-point numbers before being compressed using 7z format. Therefore, we update it in the second stage with only distortion.

Rozendaal *et al.* [6] update all parameters in both the decoder and entropy model and optimize them for rate-distortion trade-off. Therefore, we optimize them directly for rate-distortion.

Zou *et al.* [8] use overfittable multiplicative parameters (OMPs) instead of adapters after latent refinement and optimize them solely for distortion. The updated parameters are linearly transformed to a range between 0 and 255 before being quantized to integers to obtain eight-bit integer values and two real values (scale and bias) for linear transformation with a precision of 32 bits each. Therefore, we optimize it in the second stage solely for distortion.

Finally, Tsubota *et al.* [5] use matrices as learnable adapters after latent refinement and optimize them for both rate and distortion. They further adopt matrix decomposition to reduce the number of parameters. Therefore, we update it in the second stage with both rate and distortion.

2. Adapted to Other Domains

Our adapter can also be applied to images in other domains. Specifically, we evaluate on three additional domains: Comic, Line drawing, and Vector art, which are collected by [5] by utilizing WACNN [9] as the baseline. The

results are presented in Table 1. For Kodak, which is an in-domain dataset, the bit-reduction brought by the adapter is smaller than the bit-increment brought by its parameters. Yang *et al.*'s method optimizes the latent code without extra bitstreams, yielding superior results compared to ours. Nevertheless, in most cases, our proposed method outperforms the other adaptation methods, particularly when the image contains a large portion of synthetic content that are far from natural content. It should be noted that on the Kodak dataset, which is an in-domain test, our results are slightly lower than the baseline but still superior to VVC [2]. This differs from the case where Cheng2020 [1] is used as a baseline. This is because WACNN has higher compression performance in the natural domain; when an adapter is inserted, performance improvement is limited or even non-existent (the additional overhead bits outweigh the improvement in PSNR value). Figure 1 presents the results of our rate-distortion (RD) performance comparison. Our Dec-Adapter outperforms other learned compression methods when the image contains rich information and is different from the previous domain.

3. Qualitative Results

We present additional visual qualitative results comparing our method with other compression methods in Figure 2 and 3. All the results are generated with WACNN [9] as the baseline. The figures show examples of reconstructed images using our method and those of Yang *et al.* [7], Rozendaal *et al.* [6], Zou *et al.* [8], Lam *et al.* [4], and Tsubota *et al.* [5]. Our reconstructed images retain more detail at similar bit rates.
